WAR AND THE MIGRATION OF TROPICAL DISEASES

LIEUTENANT COLONEL THOMAS T MACKIE
MEDICAL CORPS, ARMY OF THE UNITED STATES

The second world war differs in one fundamental respect from any previous conflict recorded in history—the enormous potential hazard of disease to which populations may and probably will be exposed. This will probably not reach its peak during the period of actual warfare, rather in the period of population readjustments following the cessation of hostilities. War and pestilence are no new partners. On many occasions disease, far more than the operations of armies, has determined the outcome of campaigns and the course of political history. Armies on many occasions in the past have in fact functioned as traveling reservoirs of infection from which endemic and epidemic diseases have been widely spread through the civilian populations with which they have come in contact. The resulting outbreaks, however, have been more or less restricted to the zone of military operations. As the science of epidemiology has developed, the application of control methods has progressively limited dissemination. The distribution of typhus fever in the first world war is a striking illustration. Widespread in highly epidemic form in the Balkans, western Russia and Poland, it did not reach the armies of western Europe despite the fact that they too were heavily louse infested.

The problems presented by the second world war are far more complex. The theaters of operations comprise the greater part of the world's surface excepting the continents of North America, South America and Australia. The war to a great extent must be fought in the tropics and the subtropics. Immense numbers of nonimmunes are being mobilized in hyperendemic areas and subjected to the added risk of the limitation of effective control measures unavoidable in the face of combat conditions. To the classic military diseases of the past, the dysenteries, the enteric fevers and typhus, must be added many of the diseases contained within the category of tropical medicine. The magnitude and ultimate significance of the problem presented by latent infection and the carrier state among military and naval personnel cannot be evaluated. The similar problem presented by refugee peoples in mass emigrations from war devastated areas cannot even be estimated.

SCOPE OF TROPICAL MEDICINE

Two questions immediately arise. What is tropical medicine and to what extent does it differ from medicine in the temperate zone? Secondly, and much more pertinent, are not tropical diseases by definition restricted to the tropics and therefore at most of only limited significance outside the hot and humid zones?

Although no completely satisfactory definition has been reached, tropical medicine may be said to comprise a special group of diseases more prevalent in or restricted to the warmer regions, many of which are caused by protozoan or metazoan parasites, many of which require particular intermediate hosts or special insect vectors and some of which at least are limited by special factors of climate.

The limitations imposed by such special factors as intermediate hosts, insect vectors and climate, however, are of less importance in a consideration of the possible spread of tropical diseases than are the local levels of sanitation and personal hygiene. Many so-called tropical diseases have in point of fact, worldwide distribution. Malaria in endemic and even epidemic form occurs wherever suitable anopheline mosquitoes have access on the one hand to human sources of infection and on the other to nonimmunes. Such anophelines are indigenous deep into the temperate zones and clinical malaria exists in northern Europe, the British Isles, the northern United States and Canada. For the most part it is a relatively benign disease in these regions, especially since the serious tropical type caused by *Plasmodium falciparum* has not been imported in sufficient concentration. Plague, both bubonic and pneumonic, has occurred throughout the world and in epidemic form both in the tropics and in Manchuria in the midst of winter. Outbreaks have occurred in the past in various of our coastal cities. In its sylvatic form it is endemic among wild rodents on the West Coast and the Mountain states and has extended east across the continental divide. Leprosy, widespread in the tropics in the past, was distributed widely over northern Europe and Scandinavia. Between the years 1826 and 1873 four pandemics of cholera spread this disease from Asia to Europe and North America, producing epidemic outbreaks which involved most of the United States. During the first world war the disease occurred in Russia, Austria-Hungary, Germany and Italy. The freedom from yellow fever which we have enjoyed since the last outbreak in New Orleans in 1905 has caused many to lose sight of the fact that highly fatal epidemics have occurred in the past as far north as Philadelphia, New York and Boston. And the most important vector mosquito, *Aedes aegypti*, is widespread throughout the tropical and temperate zones. The rickettsial diseases are likewise no respect-

Revised for publication by the War Department Manuscript Board which assumes no responsibility other than correction for the content of this article.

cis of geographic or climatic limitations. The Rocky Mountain spotted fever group, including São Paulo fever and *fièvre boutonneuse*, are widespread in both the tropics and the temperate zone. Typhus fever is ubiquitous in its occurrence wherever conditions favor louse infestation and in certain areas is transmitted by the rat flea and certain ticks as well. Because they have long been recognized to be prevalent in the tropics, amebic and bacillary dysentery have been classified as tropical diseases. Recent experience has shown that climate is not a limiting factor and that these conditions become endemic and even epidemic when sanitary installations and exposure permit contamination of food and water and transmission from infected to uninfected individuals. Even such a strictly tropical disease as filariasis produced by the *Wucheria bancrofti* has existed in an area in the vicinity of Charleston, S. C. It is abundantly evident therefore that the implied limitations of climate on the distribution of tropical diseases are not valid and that many serious conditions may be translated from the warm climates where they are normally endemic to other areas where they have been nonexistent, or at most, uncommon.

POSSIBLE EFFECTS OF THE WAR

The worldwide spread of this war and its vast repercussions on certain population groups seem to be creating an artificial and wholly new situation peculiarly favorable for a mass migration of tropical disease and the establishment of new and important areas of endemicity. Several important factors contribute to this possibility.

Many millions of combatants will inevitably be massed throughout the tropical and subtropical regions of Africa, the Near East, Burma, Malaya, China and the islands of the Southwest Pacific. Under peacetime conditions their protection against infection would constitute an enormous problem in the fields of public health administration and sanitary engineering. In time of war, for many, it becomes impossible of accomplishment. The combination of combat conditions with the modern technic of mobile mechanized warfare inevitably reduces the measures of protection against disease to those which are applicable to the individual. This in turn necessarily entails increased exposure to infection. Preventive medicine has made great strides in the field of immunization, and these advances are being applied as rapidly as the development of knowledge makes them available. We have, for example, "vaccines" against typhoid, paratyphoid, tetanus and yellow fever the protective values of which are well established. We have vaccines for plague, cholera and typhus the efficacy of which remains to be evaluated. We have no method of immunizing against the dysenteries, malaria, leishmaniasis, trypanosomiasis and a host of other conditions to which these men inevitably will be exposed during the course of their military duties. Since we cannot prevent exposure, since scientific knowledge does not afford the means for immunization and since therapeutic measures for diseases such as malaria, typhus, the dysenteries, leishmaniasis and trypanosomiasis, among others, do not invariably, and in some instances even usually, eradicate the infecting organism, latent infection and the carrier state must be anticipated among many exposed individuals. Again armies will become mobile reservoirs of infection.

Such a "seasoned" army, in the logic of war, must carry the fighting to the enemy. It must invade occupied countries and establish itself among indigenous populations greatly weakened by malnutrition and semi-starvation. Observations of the civilian population of Madrid during the Spanish Civil War permit one to draw what is probably a reasonably accurate picture of the plight of the Axis dominated peoples in many areas. By the end of 1937 the Madrid diet consisted mainly of bread, rice, small amounts of dried pulses such as peas, beans and lentils, and a little animal protein. In 1938 the animal protein was much further reduced. The greatest incidence of deficiency diseases occurred at the end of 1937 and in early 1938. As would be anticipated from the diet limitations, neurologic disturbances appeared first and persisted from October 1937 throughout the period of siege. Pellagra presented two incidence peaks, in the spring of 1938 and again in the spring of 1939. Famine edema became a serious problem after November of 1938. The limited reports available from Axis dominated regions indicate an enormous incidence of serious malnutrition among the civilian populations. Such populations provide peculiarly fertile soil for the implantation of diseases previously not endemic among them.

The tremendous developments in aviation and the constant air transport between widely separated theaters of war provide an obvious means for the translation of disease to new areas. The speed of such travel permits the transportation of infected individuals within the incubation period of many infectious diseases and, lacking effective safeguards and constant vigilance, may well give rise to situations of immense gravity. It would be difficult to visualize a greater calamity than the importation of yellow fever to India.

These extended lines of communication and the varied means of transport create another epidemiologic possibility, illustrations of which are not lacking in the past. The importation of a necessary animal reservoir is an old story in the spread of plague about the world. The conditions in occupied areas, especially those in which extensive bombing and ground combat have occurred, are such as to favor great increase in the rodent population and to set the stage for such diseases as plague, murine typhus, tularemia and leptospirosis.

In similar fashion, importation of a necessary vector previously absent, or an unusually efficient vector, can completely alter the ecology of a disease in a particular region. The accidental importation of *Anopheles gambiae* from West Africa to the east coast of Brazil is a striking illustration. Malaria previously endemic and with low mortality rapidly became epidemic, accompanied by high mortality. Furthermore, the translation of a potential vector from one endemic area to another may be accompanied by alterations of its biologic activity or habits of such a nature as greatly to enhance its importance as a disseminating agent for disease. Such variations have been shown to exist for anopheline mosquitoes in different areas. In some regions *Anopheles albiparvus* bites man and is a carrier of malaria, in others it ignores man and is harmless. Moreover, such definite and important differences in the feeding habits of an anopheline have been observed in relatively closely adjacent areas. *Anopheles aquasalis* (*tarsimaculatus*) is a man biter and a vector of malaria in Trinidad. It is said to ignore man and to be harmless

in Panama. The reasons for such variations are not understood, yet the problems which they present in connection with mass importation of malaria into an area in which it has not previously been a major problem, and consequently thoroughly studied, are great. Control of mosquito breeding constitutes an essential part of a malaria control program. In areas where the conditions are such that ample breeding places exist, it is frequently impossible to undertake the control even of all the anopheline species. Efforts must be concentrated on the one or two important vectors. It is obvious how complicated the problem might become following the importation of an anopheline, unimportant in its area of origin which in the course of adaptation to the new environment acquired the characteristics of a competent and efficient vector of malaria.

A further possibility, not as remote as it might seem on casual inspection, lies in the potential adaptation of a strange genus in a nonendemic area to an imported disease producing agent transmitted in another region by a different species within the genus, by a different genus within the family, or even an insect belonging to an altogether different family. Such a possibility is augmented by the widespread geographic distribution of certain important insect families, particular members of which are known to transmit certain tropical diseases. Among them are the Argasidae, the soft bodied ticks, the Psychodidae, the phlebotomus or sand flies, the Simuliidae, the black flies, black gnats, buffalo gnats or coffee flies, the Chironomidae, gnats, punkies, no-see-ums, the Triatomidae, the cone nosed bugs, the Trombididae, the mites and chiggers, and the Culicidae. Members of these families in various parts of the world are responsible for the transmission of a variety of diseases, important among which are such conditions as Rocky Mountain spotted fever, fievre boutonneuse, relapsing fever, cutaneous and visceral leishmaniasis, Carrion's disease, American trypanosomiasis, tsutsugamushi disease or Japanese river fever, filariasis, onchocerciasis, the blinding filarial disease, malaria and dengue fever, and certain of the virus diseases.

The transmission of yellow fever in different endemic areas provides a classic illustration of the successful adaptation of different insects to a single disease producing agent. In addition to the familiar *Aedes aegypti*, jungle yellow fever in South America is transmitted by *Haemagogus*. In West Africa nine species of *Aedes* and certain members of the genera *Eretmopodites*, *Culex*, *Mansonia* and *Anopheles* have been shown to transmit the virus by bite. The spirochete of relapsing fever in Africa is transmitted by the tick *Ornithodoros moubata* and in the United States by *Ornithodoros hermsi* and *Ornithodoros turicata*. In these ticks the infection is transmitted congenitally to successive generations. Relapsing fever is also transmitted by the human body louse *Pediculus humanus*. The Mediterranean form of the disease due to *Spirochaeta hispanica* is transmitted not only by an ornithodoros tick but by a rodent or hard shelled tick, and the body louse as well. One of the rickettsial diseases, Q fever in Australia is spread by the hard tick *Ixodes humerosa* and in the United States by the soft tick *Dermacentor andersoni*. Mites, which are widely distributed over the world transmit endemic typhus in Manchuria and the tropical rat mite in this country has been shown to be a suc-

cessful experimental vector. Filariasis due to *Wuchereria bancrofti*, the common cause of elephantiasis has a worldwide distribution in the tropics. The larval worms have been shown to undergo complete development in a large number of mosquitoes which are indigenous to many areas outside the tropics. Common and efficient known vectors include *Culex fatigans*, *Culex pipiens*, *Anopheles variegatus*, *Anopheles rossi* and *Anopheles costalis*. A related infection, onchocerciasis is spread by at least five species of the genus *Simulium*. Recent studies of the encephalitides have demonstrated almost unlimited potentialities for wide dissemination, especially in view of the variety of vectors these viruses accept as transmitting agents. Hammon and his associates have shown that the St. Louis and western equine encephalomyelitis viruses are naturally transmitted by *Culex tarsalis*, *Culex pipiens* and *Aedes lateralis*. A reduvid bug, *Triatoma sanguisuga*, has been found naturally infected with the western equine virus in Kansas. Even more significant, perhaps, is the experimental demonstration that two species of *Dermacentor* ticks can be infected and that in these species transovarian transmission occurs to succeeding generations. The immunologic relationships between the St. Louis virus and the West Nile and Japanese B viruses and between Japanese B virus and the virus of Russian spring and summer encephalitis suggest easy, rapid and wide spread of these diseases.

In certain instances it is probable that importation of a disease agent might rapidly lead to establishment in a new reservoir host and permanent and widespread endemicity. Such host adaptation is as much a reality as is vector adaptation. Several tropical infections adopt a variety of animal hosts. Among these are included plague, which notoriously becomes endemic in a number of rodents, tularemia and brucellosis. Q fever and "nine mile fever," if not due to identical agents are closely related. The natural reservoir of Q fever in Australia is believed to be the bandicoot. The recovery of the organism in *Dermacentor andersoni* ticks indicates the presence of an animal reservoir in Montana. Reference has already been made to the variety of hosts, to which at least certain ones of the encephalomyelitis viruses adapt themselves.

AFTER DEMOBILIZATION

The late stages of the war with invasion of the Axis controlled regions and subsequent demobilization of armies and movements of civilian population groups constitute important factors in determining a widespread migration of tropical diseases. It is inescapable that members of army and navy personnel will transport foreign infections into areas in which they have not previously been endemic or important. Similarly it is highly probable that cessation of hostilities will be followed immediately by mass emigrations of oppressed civilian populations from many Axis occupied countries. Among many of these certain tropical diseases have long been endemic and others will probably have become established. Potential reservoir hosts and efficient vectors are readily available in many areas nonendemic in the past. In addition, efficient vectors may well be imported and new animal reservoirs established.

There is ample precedent for such possibilities. The vectors, moreover, are additive. If they become operative it is inevitable that they will considerably augment

the human reservoir or seed bed of disease and profoundly alter present geographic distributions. The consequent migration of tropical diseases may be extensive and will certainly exert a great effect on public health practice and the practice of clinical medicine in many parts of the world.

It would appear therefore that the United Nations must face and accept a grave medical responsibility in the oppressed areas. To the obvious and well recognized need for provision of foodstuffs and clothing to combat the malnutrition, semistarvation and destitution must be added the imperative need for effective control and treatment of disease. The control of tropical diseases may play a most important role in the successful discharge of these responsibilities.

DISCUSSION

DR. HENRY I. MEYER, New York. It has been shown by Georgy of Cleveland that rats on a deficient diet in many cases are more susceptible to the multiplication of lice on their bodies, this may apply to man. Bessy and Pinkerton showed that rats on a deficient diet were more susceptible to endemic typhus virus and succumb much more rapidly than those on a normal diet. Professor Matherson of Cornell, an eminent entomologist, recently called attention to the fact that *Rhipicephalus*, one of the dog fleas which has been known previously only in South and Central America and in Texas, has during recent years extended apparently on dogs as far north as New York State and New England, this is one of the vectors of spotted fever. He also reported that a medical officer in the Army stated to him that he had seen airplanes landing on the Texas border from which insects in large numbers were discharged from the undercarriage when the wheels were let down for landing. This apparently is not a harborage of insects which has received great attention by immigration and army authorities in the transportation of insects from one country to another. It is also well known that *Xenopsylla cheopis*, the tropical rat flea which is the principal transmitting agent of the plague and of murine typhus, has been extending in this country from the Southern states northward into the Central states. This is probably the chief or only vector of endemic typhus or Brill's disease, even in New York City.

We already have in New York a number of cases coming from Africa of estivoautumnal malaria. It is possible that the strains of that parasite from Africa are more virulent than those that we have in the United States. We have the vectors of malaria in at least the suburbs of New York City and certainly all through the northern United States. It is easily possible that more virulent strains of *Endameba histolytica*, perhaps such as those occurring in the Chicago epidemic, which was water borne, will be imported from Africa to this country by our troops and be the seeds for extensive epidemics occurring under insanitary conditions of plumbing in this country. Finally, we have to think of the possibility of our enemies deliberately introducing infected vectors or at least vectors of disease into areas in which we shall be operating. The Japanese have already been accused of dropping plague infected fleas in China. It is interesting that the islands of the Pacific, which were under Japanese mandate before the war, are almost entirely free of *Anopheles* mosquitoes and therefore free of malaria, but it is possible that either by accident or by deliberate action *Anopheles* mosquitoes might be introduced into those islands when the Japanese abandon them, or that even Hawaii might be exposed to *Anopheles* and introduce malaria where it has been absent.

These are concrete illustrations of the potentialities of the spread of disease from the tropics to temperate zones. It is worth noting that this country itself is not without the possibility of spreading such diseases which come back in our combat troops, even to Central and South America.

EPIDEMIOLOGY OF INFLUENZA

THOMAS FRANCIS JR., M.D.

Professor of Epidemiology and Chairman of the Department of Epidemiology, School of Public Health, University of Michigan
ANN ARBOR, MICH.

The long history of influenza scarcely warrants its consideration as a wartime disease. But, because of the great frequency of military operations and the numerous occurrences of influenza, little juggling would be required to show that outbreaks of the disease have synchronized with one or another of such disturbances. Nevertheless the severe outbreaks of 1830-33, 1836-37 and 1847 were not accompanied by major international strife. The pandemic of 1889-90, occurring in years of apparent Victorian tranquillity, was however, associated with one of the greatest calamities of modern times—the birth of Adolf Hitler. Despite the fact that war and influenza had not been historically related, the appalling pandemic of 1918 in the last months of an exhausting conflict has served irrevocably to indicate that virulent influenza coinciding with the massive upheaval of a population through war may be more devastating than war itself. In a period of a few months 20 million people perished, 548,000 in this country alone, the number attacked was 50 times as great.

The profound impact of that devastation has left the impression on many sides that the pandemic of 1918 was the true picture of influenza. It is a peculiar situation in which the most unusual episode in the history of a disease would be considered the typical. It might be asked with greater reason whether the 1918 occurrence should be called influenza. Consensus of opinion, however, has concluded that in its major features the pandemic of 1918 resembled that of 1889-90 and the succeeding years as well as the later ones of 1920 and 1926. According to Jordan, the features on which these conclusions are based are "the agreement in high morbidity, measurable increase of pneumonia mortality and general clinical resemblances." Again "The chief distinctions between pandemic influenza and inter-pandemic influenza appear to be that the former is disseminated rapidly over a wide area while the latter is more limited in its distribution and appears to spread from point to point more slowly, if at all, that the effect on the mortality from pneumonia and tuberculosis, and on the birth rate is usually less marked than that of the pandemic disease, that the age-specific mortality rates are different and that the prevalence of the pandemic disease is not notably influenced by weather or seasonal conditions." The differences enumerated appear to be those of degree—quantitative differences of broad epidemiologic rather than of specific clinical or etiologic nature. Application of the same criteria to the pandemics of 1889-90 and 1847 reveals significant variations between them and the 1918 experience. If the latter, therefore, is accepted to be essentially the same disease as the other occurrences mentioned, it seems reasonable to include epidemics of the past ten years as well. Instead of classifying outbreaks of similar clinical and epidemiologic appearance as separate diseases according to severity and extent, influenza would be considered a disease possessing basic, essential characteristics, varying in amplitude and clinical severity.

Read before the National Conference on Planning for War and Post-war Medical Services, New York, March 15, 1943.

in different visitations and caused by agents of similar pathogenic properties which may differ qualitatively and quantitatively. This concept of the epidemiology of influenza tends to bring it into line with principles which underlie the ebb and flow of other epidemic diseases of man transmitted by the respiratory route. In addition evidence gained through etiologic identification of the disease in recent years appears to fit that pattern.

RECENT EPIDEMICS

Ten years ago Smith, Andrewes and Laidlaw reported from England the isolation in ferrets of a virus from patients observed during an epidemic of influenza. In the late summer of 1934 their evidence was first corroborated by the recovery in this country of a strain of the same virus from a widespread epidemic of influenza in Puerto Rico and as the disease spread across the continent during the winter and spring, from cases in New York, Philadelphia, New Haven and Alaska. In July 1935 virus was isolated from an outbreak in Australia. Since that time investigations have extended to all parts of the world and many facts concerning the disease—now called influenza A—and the virus have been disclosed. Up to now each second year has witnessed the prevalence of influenza A.

In December 1936 a sharp epidemic of influenza A was identified in New York City and spread rapidly thereafter through the United States. At about the same time the disease was recognized and became widely disseminated through Europe, eastern Russia, China and Japan. Virus of the same type was recovered in laboratories operative in all these areas. Moreover there was agreement among observers that the disease possessed the attributes which led unhesitatingly to the diagnosis of influenza. The onset was sharp, the epidemic climbed rapidly to a peak and subsided promptly, the incidence was high, though not accurately determined, and the case fatality was low. The clinical picture was relatively uniform with a moderate number of pulmonary complications. That the virus was virulent is shown by the fact that it was readily transmitted to experimental animals of various species. It seems warranted, therefore, to consider the epidemic of 1936-37 an example of a pandemic distribution of influenza.

In 1938-39 influenza A was again present in this country and in Europe during the winter season. It differed from the preceding prevalence in that the general incidence was slight and owing to the scanty distribution through the general population, the epidemic tendency was most evident in institutional groups under close observation. Nevertheless patients presented essentially the same clinical picture as that seen in 1936-37. The mild character of the human disease was reflected in the low pathogenicity of the strains for experimental animals. In July 1939, however, Australia, which significantly had escaped the 1936-37 pandemic, witnessed a widespread moderately severe outbreak in the general population and influenza virus type A was readily obtained from affected persons.

Once more in 1940, influenza A was recognized in the West Indies and South America during July and August and somewhat later in Australia and Hawaii whence it reached the western United States and spread progressively eastward in the winter of 1940-41. In England a scattering of cases was noted. The strains of influenza virus type A recovered in our laboratory

were of moderate pathogenicity, but those which were isolated in England and Australia were said to possess little virulence for experimental animals.

Thus from late 1938 through the early months of 1941 reports from observation posts in different parts of the world tend to indicate that instead of a number of unrelated mild occurrences there was a somewhat continuous prevalence of influenza A traveling in a circuit irregularly related to the colder seasons in the temperate zones but present in the summer months of subtropical areas.

In a period of five years influenza A varied in its appearance from a sharp pandemic distribution to what in terms of the larger geographic area might well represent an endemic state with intervening epidemics of moderate degree.

In addition to the five established occurrences of influenza A, two well distributed prevalences of respiratory disease were encountered which clinically and epidemiologically resembled the previously identified epidemics of influenza. The first of these was originally recognized in California in January 1936 and extended eastward through the United States. It was impossible however to obtain any evidence relating it to type A influenza virus. In the first months of 1940 a moderate epidemic was observed in the Southeastern states, but again etiologic studies failed to show a relationship with influenza A. Shortly thereafter as the disease appeared in New York, a new strain of virus was recovered which was adapted to animals with great difficulty and was shown to be quite distinct antigenically from influenza virus type A. It was called influenza virus type B. By serologic means it was then demonstrated that epidemics of 1936 and 1940 in the United States were influenza B. A strain of virus recovered at the same time by Magill has also been shown to belong to type B and the influenza of that year in other parts of this country has been clearly established as influenza B. In addition the disease was found to have appeared in the West Indies in the summer of 1940. Subsequently evidence has been obtained that the virus was circulating in Australia in 1938, New York in 1938-39, Minnesota in 1939, England in 1939 and Argentina in 1941.

The disease influenza B obviously has been world-wide in distribution. Moderately severe epidemics have been related solely to this type of virus, in other prevalences of a milder nature it has been causally related to the outbreak but not present in the majority of cases selected for study, still other outbreaks of influenza have been shown to be made up of interspersed cases of influenza A and influenza B. In addition, most observers have noted occasional instances of serologic responses to virus of both types, although no other evidence of simultaneous double infection is yet at hand. The variations in distribution of influenza B have extended therefore from nationwide outbreaks of moderate severity to those resembling a mild endemic disease.

No sharp clinical and epidemiologic differentiation between the two diseases is available at the moment nor has any well defined difference in the pathologic changes induced by the two types of virus been recorded. Immunologically they are however quite distinct. Infection with one elicits neither specific antibodies nor immunity to the other; repeated inoculations tend to induce cross reactions between them. The anti-

gen which reacts in the complement fixation test, while common to dissimilar strains of the same type does not react with serum of heterologous type. From the point of view of immunity, therefore, the two diseases must be considered independent factors in the epidemiology of influenza.

THE VIRUS AND IMMUNE REACTIONS

The relative inconstancy in virulence and pathogenicity of the virus of influenza A might well be considered sufficient to account for the modifications in scope of its recurrences if the different strains of the virus were serologically identical. But in 1936 Magill and I were able to demonstrate that this is not the case.

variants of such diversity that they can be distinguished by serologic and cross immunity tests have been identified. Throughout the studies the suggestion appears that strains present in the outbreak of one year more closely resemble one another than strains recovered in different years. That they are members of the same type, however, is shown by the fact that an adequate course of immunization or a full serologic response to one strain embraces practically all others. The type relationship is further demonstrated in that the antigen which participates in the complement fixation reaction is the same for all strains of type A but differs from that of type B strains. The extent to which antigenic variations of this degree may account for reappearances of the disease is not established, the likelihood must be seriously considered. The immunologic distinctions between the viruses of types A and B are, however, so sharp that the prevalence of one would be uninfluenced by specificity immunity to the other.

Despite the strain and type differences, the characteristics of the disease produced remain so similar that the agents may be considered a pathogenic unit. Infection is induced by way of the respiratory tract, where, after an incubation period of twenty-four to forty-eight hours the epithelium of the respiratory passages is selectively attacked and destroyed following which the extensive pneumonia of the fully adapted experimental disease develops. That the severity of the disease may be decidedly enhanced by the addition of pathogenic bacteria has been clearly demonstrated by Shope's studies in swine influenza and the observations with human strains and hemolytic streptococci in ferrets. Recently Glover has reported that hemolytic streptococci were transferable by the air route to normal ferrets from animals infected with the two agents but not from ferrets infected with the bacterium alone.

The animal which recovers from the virus disease develops circulating antibodies to the virus and a stanch immunity which persists for a period of months and then wanes to leave a modified resistance. In this stage the animal responds to reinoculation with fever and nasal signs and the respiratory epithelium is again destroyed but the typical pulmonary lesions do not develop. On the other hand, animals which have been repeatedly inoculated develop a broader resistance which persists for a longer period of time and which, serologically, is effective against more divergent strains. There is reason to believe that the susceptible tissue is also modified so as to be more resistant to virus attack, under which conditions dependence on antibodies would decrease. The human subject responds to infection with the development of circulating antibodies and presumably with immunity. The duration of immunity

in man is not known, but presumptive evidence indicates that an acquired resistance exists for a year or two at least. Nevertheless the fact that a high percentage of individuals possess antibodies to virus of type A and that a large proportion of those who take sick have circulating antibodies at the time they become infected is a clear indication that antibodies acquired through previous infection with virus of the same type do not bestow an immunity of prolonged duration. It has been observed, however, that in general the antibody titers of patients in the acute stage of illness are lower than that of the average individual who does not take sick and the natural suggestion is that resistance is proportionate to the antibody level.

Inoculation of virus by routes other than respiratory does not, but for exceptional circumstances, produce disease. On the contrary, among experimental animals it results in the acquisition of resistance and the appearance of antibodies. In the human subject antibodies are also stimulated and the assumption is that resistance is thereby increased. This inference is supported to some extent by direct experimental infection of human subjects and the observation that those individuals in whom infection was induced constituted in the main those with the lowest titers of circulating antibodies.

MORBIDITY AND MORTALITY

The speed of development of an influenza epidemic and its rate of dissemination are attributable to the short incubation period of the disease and the numerous sources of infection afforded by frank cases, persons in the incubation period of the disease or in convalescence, and a relatively high proportion of subclinical infections. From patients in each of these stages virus has actually been recovered. Moreover, the incubation period of twenty-four to forty-eight hours has been thoroughly established by accidental and purposeful infection with virus. Morbidity is related to the infectiousness of the virus and to the number of susceptibles made available through births, migration and the increment of the population which has lapsed from immunity to relative susceptibility. Obviously, that proportion will vary inversely with the virulence of the virus. Using different strains of influenza virus type A for experimental infection of human subjects, Smorodintseff and his collaborators noted 10 per cent clinical disease, Chalkina 20 per cent, Bunnet and Foley 20 per cent and Stokes and Henle 35 per cent. With a modified strain of the same type we failed to observe any clinical signs of disease, though serologic responses occurred in part of the test group. The varying incidence of the disease, therefore, does not of itself denote a different cause.

Contrary to common opinion, influenza does not most commonly affect adults. Where proper data are available the evidence shows that in the epidemics of 1918, 1920 and 1928 and the epidemic of influenza B in 1936 the highest attack rate occurs in the ages below 15 years and that thereafter a gradual decline in incidence takes place. If the presence at different ages of high titers of neutralizing antibodies to influenza A virus is taken as an index of recent infection, the same trend occurs. The fact that the majority of individuals, including children and adolescents, escaped infection suggests that the disease of 1918 was etiologically related to earlier infections which were responsible for the immunity.

On the other hand, age distribution of case fatalities in 1918 follows another curve. In children, among

whom morbidity was highest case fatality was lowest, in the higher ages, in which incidence was lowest the highest case fatality occurred, while in the intermediate years both high incidence and high case fatality were observed. Morbidity and mortality are therefore independent measures which may vary in different epidemics creating wide differences in scope and severity. The former depends on the infectiousness of the virus, the latter on the extent of the primary injury, the virulence of accessory bacterial agents—in brief on the severity of the pulmonary complications. They scarcely constitute bases for suggesting fundamental differences in the causation of the disease.

Pandemic influenza seems therefore to represent in most respects a modification of a disease caused by a virus similar to those at present identified rather than an unrelated infection arising spontaneously in a population. The influences which determine the transformation are not fully known. A number of complementary variables decide the character of an epidemic. A change in virulence, a modification in type or strain of the virus or the prevalence of pathogenic bacteria may, each or all, contribute to the effect and must be considered in preparing to meet such an event.

CONTROL MEASURES

Efforts toward control have centered to a large extent on the development of a satisfactory vaccine for subcutaneous administration. Although resistance can be produced in animals and antibodies induced in man by a variety of preparations, evidence of the protection of man against the natural disease is inconclusive. There are, nevertheless, suggestions that the severity of the disease may be reduced and the complications limited. This of itself would be no mean advantage. Even if it should be true, one is confronted with the problem of variations in the virus and the possible necessity of incorporating in the vaccine virus similar in composition to the one in circulation. For this reason it is necessary to be on the alert for earliest evidence of the nature of an outbreak. If the virus could be isolated quickly, its introduction into a vaccine would not be difficult. But the time relations are extremely important.

In addition to subcutaneous vaccination, the possibility of passive immunization by the use of serum intranasally is being explored. For this purpose serum can be collected beforehand or obtained from convalescents early in the epidemic period and used on other exposed susceptibles. Intranasal vaccination with virus itself offers another approach.

A different concept of control is presented in the form of physical or chemical barriers which serve to prevent the transfer of infectious material, viral or bacterial. Of these the aerosols offer the greatest promise because of the simplicity of their application and their adaptability to a wide variety of conditions under which crowding and air contamination are extensive. The efficacy of sulfonamide compounds furnishes great confidence that the serious bacterial complications will be susceptible to treatment and that the attendant mortality can be greatly reduced.

It is not possible to discuss the experimental data concerning relative merits of the different procedures. These comments serve only to show that efforts are being made on various lines to seize the offensive. If one or more of the procedures should prove of value in controlling influenza in its current appearances the

probabilities are that the same principles will be applicable in combating the more severe prevalences of the virus disease. For these reasons efforts must be continued and intensified.

THE WARTIME PROBLEM

Any attempt to prophesy what may occur becomes a confession of inability to define the specific circumstances which determine the severity of an expected epidemic of respiratory disease. We have witnessed on all sides the dislocation of population through the mobilization of troops, the crowding of civilians into industrial areas, the introduction of large forces into distant lands and the maintenance of the peoples of overrun countries under abnormal conditions of food and shelter. Despite these violations of epidemiologic tenets the common infectious diseases have continued to decline without notable outbreaks. There is no assurance, however, that this state of quiescence of infectious agents will persist or that under continued physiologic stress the mechanisms of resistance will not be impaired.

Increasing penetration of areas with which inhabitants of the temperate zones have had little experience and the disturbance of native equilibriums induced thereby constitute major dangers. Such invasions may serve to stir up strains stabilized in a given environment which in fresh hosts may prove highly virulent. Theobald Smith has stated that "most epidemics or pandemics are probably due to strayed parasites from either near or more distantly related hosts or from an immune group to a susceptible group of the same species or race." The eruption of such a strain would find conditions for dissemination highly satisfactory by virtue of the speed of travel and the massing of groups of individuals, presumably more susceptible because of their relative freedom from disease in recent years. An occurrence of this nature would impose a serious strain on the morale of a nation concentrated on the winning of a war. A resurgence of bacterial infections of the respiratory tract should also be taken as a warning that with their aid even milder strains of virus might produce serious disease. Nevertheless it is possible in view of recent advances, to look forward with greater confidence to the control of an epidemic than has previously been the case.

There is a peculiar fatalism toward respiratory disease except for the severe visitations they are too commonly considered inevitable. The increased interest of the past twenty years is an expression of growing dissatisfaction with the discomforts and economic losses they entail in all parts of the world. If the apprehension which the threat of serious epidemics arouses could be directed into concerted and sustained investigations in the intervening years, definite improvement in the usual status would take place. Among other aims adopted for the postwar period might well be included freedom from respiratory disease.

None of the plagues have been extinguished. Should misfortune bring back certain conditions these plagues would reappear from some remote or near corner where they are slumbering in a resistant population. The final suppression presupposes a world organization of human society without wars and disarmed such as the most pronounced idealist of today can scarcely conceive but toward which human society must tend to survive in the struggle with animal and plant life, microscopic and ultramicroscopic. Theobald Smith said that in 1934

DISCUSSION

DR. WATSON G. SMITH, New York. Pandemic influenza is the most distinctive of all epidemic diseases and the most devastating. It certainly is one of the most dramatic. This is paradoxical since the fatality rate in pandemic influenza is relatively low. But the disease is so infectious that the rate of incidence in the invaded community itself is very high. There is remarkable rapidity of spread of the disease and a high degree of communicability. In this it outranks all other contagion. The disease appears, as Dr. Francis has said, in great pandemic waves and interspersed with local epidemics. It may appear now here as it represents a group of diseases rather than a single disease. There is one striking characteristic of influenza perhaps the most striking of all and that is its unpredictability. We have really no definite evidence that indicates that pandemic influenza is the same or even closely related to interepidemic or epidemic influenza.

We have no definite evidence that an epidemic pandemic of influenza is pending. We have fairly good reason to believe that there will be no epidemic of influenza this season but we can be sure of only one thing and that is that sooner or later a pandemic of influenza will appear. We can be sure too that we are at the present time building a highly nonimmune population for influenza is not as prevalent a disease as we think. I was forcibly struck by this fact in the vaccination of some thirty thousand students at Ithaca with influenza vaccine, which was conducted this winter. We asked each one of these boys if they had ever had influenza or influenza-like disease. I was suddenly aware of the fact that these young men of this generation have not had influenza. Practically all the faculty remembered well of course the pandemic of 1918 and could describe their experience but the young men of this generation—and it is now of course a full generation being twenty-five years since the last great pandemic—have not had influenza.

It is rather what we do not know about this disease than what we know that is of great importance. What do we not know about influenza? Where does it come from? Why does it spread with such rapidity and virulence? Why does it stop? Certainly there is nothing that man has been able to do or to devise that would check the spread of the disease or lessen its virulence. Much information has been determined about epidemic influenza in the last twenty-five years. We have learned that the disease spreads through the air, but only for a short distance. Wells's studies have shown that in a closed air chamber the virus will remain suspended in the air for at least two hours without losing its virulence. There is some hope that there may be a reduction of intensity of exposure to the virus if the air may be sterilized in an enclosed building, as shown by Dr. Robertson in his air zone work, where large numbers of people are assembled, as in barracks or on transports, in theaters, office buildings, schools and the like. There might be some hope of checking the degree of exposure by this technique, but in the face of a great pandemic this method would have little usefulness.

The only real hope, obviously, of checking the spread of the pandemic would be the building up and the development of an immune population. In theory and by analogy this would seem quite feasible, but the great difficulty is that we have no certainty as to just what the cause of pandemic influenza is. It is my strong feeling that Dr. Francis is right when he says that in all probability it is closely related to epidemic influenza. One of the reasons I think so is that I was in a tropical community at the time of the last great pandemic. Those of you who have experienced influenza, the pandemic influenza in this country, have no conception of what pandemic influenza means in a tropical or in an isolated community. It sweeps the whole population before it, and the city in which we lived became a city of the dead. Not a wheel turned, not a factory ran, not a physician was on his feet. The place was devastated. It was like the story of the Great Plague, and all that one could hear would be an occasional wagon going by in the street with the old bell and the man shouting "Bring out your dead!" It was not at all as Dr. Francis indicated, it was not in relation to age distribution of the disease. The data that he mentioned

were collected in a temperate zone and in a civilized community. But in areas, isolated areas, where pandemic influenza struck, all ages were affected to a like degree. Once I visited the village of Okkak on the Labrador coast. When pandemic influenza struck that village it wiped it out. The Moravian missionary and his wife told me that they spent the winter there with a village of the dead. Where a community has had a certain degree of exposure in the temperate zone, a civilized community, a relative degree of immunity is built up. This makes one think that there is a mosaic of overlapping antigens which produces a relative degree of community immunity to epidemics.

We have new experimental techniques, we have new knowledge, particularly do we have a newer understanding of the nature of virus diseases. All this has developed in the past twenty-five years. Certainly we are ready to attack influenza intelligently when it comes. It probably will require at least one more great pandemic before the true nature of this disease can be determined. There is little reason to hope that any effective means of prevention can be developed before that time.

MALARIA AS A WORLD MENACE

L. T. COGGESHALL, M.D.

Professor of Epidemiology, School of Public Health,
University of Michigan
ANN ARBOR, MICH.

The subject of malaria as a world menace at the present time should not imply that this is a controversial topic. During more normal periods it is generally considered that malaria is the most prevalent of all diseases and probably ranks foremost as a cause of morbidity.

Many have prophesied the complete control, or even eradication, of malaria on the basis of the fact that the plasmodia and their vector, the anopheline mosquito, are vulnerable to attack at many points in their complicated life histories. But thus far the methods of malaria control designed to destroy or curb the larval and adult development of the malaria-carrying mosquito, the attempts to quarantine man from the mosquito and to prevent or cure the disease in man by chemical agents have not, singly or in combination, succeeded in removing malaria as a world problem. As Surgeon General Parran of the United States Public Health Service has recently stated, "outside of the mental diseases there is no other disease of comparable importance against which we have made less progress during my generation."

Accurate figures on its morbidity and mortality are not available, but a few of the more carefully prepared estimates furnish ample evidence that it is one of the great medical problems of our time. In India the director of the Malaria Survey reported in 1935 100 million cases resulting directly in a million deaths. A thorough study of a recent epidemic in Ceylon revealed that in a population of 5 million persons there were 1½ million cases, resulting in a mortality of seventy thousand. This epidemic occurred in a country in which the endemic rate ordinarily is not appreciably less than the epidemic rate. It is not unusual to read reports of malarial surveys in countries where the rate of infection is 100 per cent of the population. In the United States it is probable that there are a million cases annually, resulting in five thousand deaths, although inaccurate diagnosis and lack of proper vital statistics make this a very rough estimate.

Read before the National Conference on Planning for War and Post War Medical Service, New York, March 15, 1943.

ASSOCIATION OF MALARIA WITH WAR

All the conditions which enable the disease to maintain this unenviable position are present during wars and in addition a new group of epidemiologic factors appear which greatly accelerate its acquisition and dissemination. There is such a close association between war and increased malaria that the term "war malaria" has become justifiable. This relationship with its disastrous effects can be demonstrated in practically any war, but the malaria of World War I furnishes all the needed examples. At that time the malarial problem was unusually severe in the Italian, East African, Mesopotamian, Palestinian and Macedonian theaters of operation. The British troops were in Macedonia early in 1915 and by June they had only 90 cases of malaria. However the number steadily grew and during 1916 they had at least 30,000 men down with the disease. By 1917 the number had increased to 70,000 and in 1918 they invalided home 25,000 of the more serious cases. In the same area the French had only 20,000 able bodied men in a force of over 100,000. As a matter of fact the commanding general informed the War Office that his army was hospitalized with malaria. Fortunately the Central Powers fared no better. In the other areas cited, the same situation prevailed and approximately 25 per cent of the personnel of the opposing armies were acutely ill with malaria a major portion of the time.

Malaria does not confine its effects merely to the war zones but invades the homes of the returning soldiers. Again in the last war secondary cases appeared throughout England, and on the North German coast at Emden there was an epidemic of 6,000 cases. In Russia one of the greatest malarial epidemics in modern times developed in 1923 among the impoverished civilian populations. The Red Cross reported 3 million cases in the republic west of the Ural Mountains. Some cases appeared in Archangel and, as Hackett states "for the first time, as far as we know, the King of Tropical Diseases set foot within the Arctic Circle." Thus we see illustrated from this brief account of malaria in the last war the two great problems, first the acquisition of malaria in epidemic proportions in the military forces, second and more important, its scattered transfer to the larger susceptible reservoir of civilian hosts.

Our experience in World War I did not impress us with the seriousness of the malarial problem because our troops were primarily concentrated in the non-malarious zone of northern France. Actually there were only thirty-six deaths officially credited to malaria from April 1917 to November 1919. The highest case rates came from noncombat areas and for the entire war there were only 88 per thousand from Panama, 25 per thousand in the Philippines, 4 per thousand in the United States and 0.4 per thousand in Europe.

In the present war we have already felt its grave effects. At the fall of Britain, for example it was estimated that 85 per cent of every regiment had acute malaria. Contrast this figure with the 25 per thousand in the Philippines during the last war and you can see the difference between combat and peacetime operations or, rather, the difference between the last war and the present one. More than 50 per cent of our men have contracted malaria during their relatively

short exposure in some of the islands in the Southwest Pacific. In Africa malaria has been one of our principal medical problems and many have already been invalided home because of repeated attacks. This is just a start and as time goes on we cannot expect that the malarial picture will wane.

FACTORS MAKING MALARIA AN IMPORTANT HAZARD

Let us analyze the various factors that make malaria the outstanding hazardous medical problem of the current and postwar period. Undoubtedly the most important factor is the location of the troops. Men have chosen some of the worst disease-ridden corners of the earth as theaters of combat. A major proportion of our troops overseas is in tropical areas in close contact with the huge native malarial reservoirs. If we ever approach the proposed figure of eleven million men in the armed services, which means practically one half of our adult male population and if the same proportions are to serve in the tropics as now then we can gain some appreciation of the probable consequences. The men will be located in Africa, the Middle East, China and the Southwest Pacific where cursory surveys reveal a major percentage of the civilian population affected with malaria. For example, in Liberia 90 per cent of the children under 5 years of age have positive blood smears, most of them harboring the gametocytes necessary to infect the mosquitoes. Many die before acquiring resistance to the disease. Even 70 per cent of the adults are continuously infected. These adults represent the survivors and have developed a tolerance for the disease, as they are in apparent good health yet maintain an intensity of infection that would incapacitate the white man. The rates cited in Liberia are not excessive for most of the other tropical areas. Not only are the large infected reservoirs available but also the other requisites for transmission, namely efficient vectors in excessive numbers. The most dreaded vector of all, *Anopheles gambiae* is particularly prevalent in Africa. It is a domestic mosquito and constantly migrates between the source of infection in the native huts and the barracks of the susceptible soldiers. In other places there is no lack of available vectors particularly in India, where there are probably twelve suitable species. The combination of infected reservoirs, accessible efficient vectors, climatic conditions favorable for year-round transmission and a ready supply of susceptible hosts can only result in a high incidence of malaria in our army. As mentioned previously, reports from the various war areas show that our forces are acquiring malaria at an excessive rate, probably more cases per day than we experienced per year in the last war.

ATABRINE AND QUININE

The administrative medical officers of our armed forces have realized the danger and for the first time are making serious efforts to curb the infection. Malarial survey and control units are being formed given special training and sent to the battle areas where the problem is most acute. In these combat zones control efforts will largely be limited to the use of nets, insecticides, sprays and suppressive drugs. In spite of the most efficient application of these measures it will be difficult to diminish the incidence appreciably. Even

in many static areas the problem is not easily solved in spite of the fact that the malariologists are applying every control method known. The medical officers are handicapped by certain deficiencies of their tools, particularly in prophylaxis and treatment. We now have available only atabrine for its suppressive effects of the clinical symptoms of malaria as the limited supply of available quinine must be used for treatment. Recently considerable emphasis has been given to the fact that atabrine does not prevent the inception of malarial infection but only its acute manifestations. Actually it is not a perfect suppressive drug. For example during a carefully controlled investigation in a highly endemic region of West Africa late last year Findlay found that there were 125 clinical attacks of malaria in 322 men, or 45 per cent, between July 1 and November 6 and all had taken the prescribed prophylactic dose of 0.4 Gm per week. With the exception of Corregidor and Bataan, where no drugs were available near the end, all of our excessive rates are occurring in men taking atabrine routinely. Quinine likewise is only a partially effective suppressive drug.

When used for their therapeutic effect neither atabrine nor quinine will eradicate an infection. They merely control the acute attack and if an individual succeeds in throwing off the infection, it is by the effort of his own defensive mechanism. Some attention has been given to a recent article entitled "Enter Atabrine, Exit Malaria." A more appropriate title would have been "Exit Quinine, Enter Atabrine," as atabrine is as effective prophylactically and therapeutically as the rapidly diminishing stock of quinine, but it will not cause an infection to disappear. It is clearly evident, therefore, that as yet we have no drug that will prevent or reduce the large volume of malaria that is constantly increasing.

FURTHER OUTBREAKS

If the damage were solely confined to the troops in the affected areas the problem would be serious enough to cause considerable apprehension. Unfortunately this is just the initial step in the chain of events that is likely to create a more serious disaster. The return of infected troops to hospitable territory is likely to result in the initiation of serious epidemics, especially in those places where control efforts are lax because of the absence or low incidence of malaria. We have already referred to the secondary eruptions which followed the last war. At the present time we can expect more serious outbreaks if for no other reason than the increased number of infected cases. In the United States during the past few years there have been minor spontaneous outbreaks of malaria in northern California, Iowa and Connecticut. The origin has occasionally been traced to infected fruit pickers who live a nomadic life in trailers and follow the summer seasons northward. Their environment is always a tropical one. More serious disturbances have probably not occurred because the infected persons have been too few in number. Sir Ronald Ross pointed out years ago that there is a critical ratio between the number of infected cases and mosquito vectors below which the infection would die out, or a relatively small change in the ratio might produce striking changes in the malaria incidence. Throughout the United States we have an abundance of *Anopheles quadrimaculatus*, the important mosquito

vector for this country. It thrives as far north as the Canadian border and thus the stage is all set for trouble. We have the susceptible population and the vector, and the disease seems to be on its way.

Although we have a good vector for malaria in this country and it will transmit any of three human plasmodia, there is also danger that new vectors may be introduced. It might be pertinent to question whether the mere introduction of another species would alter the picture. This can be answered by the events that transpired in Brazil in 1930, when *Anopheles gambiae* was accidentally introduced. There soon followed a malarial epidemic which cost at least 14,000 lives in one year with more than a hundred times that many cases. Both malaria and vectors were already present in the same region, but this introduced species of mosquito multiplied at a prodigious rate, as it had left all of its natural enemies behind. By its numbers, therefore, it had disturbed the normal equilibrium and supplied the flame needed to ignite the ready fuel. This mosquito would probably behave in the same way should it be introduced into this country because the climatic conditions in some of our Southern states are not too different from some of its natural habitats in Africa. This is only one of the hundreds of similar possibilities. The Hawaiian Islands and our West Coast, for example, have always been practically free from malaria but now they are the terminus for a huge air traffic originating in the Southwest Pacific, where the disease is rife. It seems quite unlikely that the islands can escape an epidemic that can result in a public health and economic disaster.

It may also be pointed out that it is unlikely that malaria can be a cause of much trouble in this country since the disease is already indigenous, particularly in the South. Unfortunately, the tolerance a population develops against a strain of malaria by virtue of repeated infections confers little immunity against strains from other areas. Experimental studies in cases of dementia paralytica show that an individual is immune only to that strain with which he has had previous experience. Strain or species specificity has often been noted in armies, particularly native troops who have acquired considerable tolerance to malaria in one area yet acquire multiple acute attacks when moved to other highly endemic areas.

The biologic behavior of a malarial infection aids in perpetuating the disease, as it has a tendency to produce chronic infections with frequent relapses. It is estimated that falciparum malaria, the most virulent species, has a relapse rate of approximately 20 per cent and that in spite of most vigorous treatment this percentage cannot be lowered. Vivax and quartan malaria relapse more frequently, and the infections may persist for years. As yet there is no vaccine that will immunize an individual against malaria. It is highly doubtful if an effective one will be discovered, because the disease itself produces only a state of premunition, which means that the host is immune only as long as he harbors the infection. Even then he can resist infection only to the homologous parasite. Actually it is possible for an individual to have the three human malarial infections in the same year or subsequent attacks produced by different strains of the same species. Thus the mass rehabilitation and dispersal of sick troops allow for the

establishment of epidemics over long periods even in malarious areas and there is no means of halting the spread by immunization procedures

ANGER FROM AIR TRANSPORTATION

Another epidemiologic factor confronting us for the first time and providing a means of breaking down existing barriers is the speed and volume of modern air transportation. We are living within sixty hours of any part of the earth. With the exception of the route to the British Isles practically all of our foreign air traffic is now originating in the malarious areas of the tropics—in the Southwest Pacific South and Central America, the Caribbean area Middle and North Africa, the Middle East, Russia India and China. The airports in these places are usually located in the insanitary areas—frequently only a metal strip runway in a hacked out portion of the jungle. No matter how remote, they are usually surrounded by native villages whose occupants are being utilized as laborers and serve as sources of infection. Literally scores of these airports are being constructed, and the menace to the passengers troops and large personnel necessary to maintain aircraft operations is a serious one. Many infections can be acquired and be transported back to malaria-free zones before the incubation period has elapsed and thus avoid detection. Another danger is the transportation of mosquito vectors which has already been known to occur in spite of the vigorous efforts to destroy them by spraying the planes with insecticides.

SUMMARY

We must conclude that the potential danger of malaria during the present war is a greater worldwide menace than ever before. How can we prevent this possibility from becoming a reality? For the present, more energetic application of accepted methods of control must be the rule. We need not accept past failures as inevitable, but a more widespread recognition of the danger can result in more effective control effort. The stimulus will come from the secondary outbreaks traceable to imported infections. At the first sign of such episodes an all out effort should be instituted by local, state and federal authorities. If this is done early, the danger of spread can be averted. The severe Brazilian epidemic cost the Brazilian government and the Rockefeller Foundation approximately \$2,500,000 to eradicate *Anopheles gambiae*—certainly a cheap price, at least when compared to the economic loss that would have resulted if that species of mosquito had not been destroyed, as it was spreading rapidly to new areas. It is an example of what can happen and what can be done and is a major achievement that will go down in the annals of preventive medicine.

The long-term policy must include more training centers and opportunities for fundamental research. These places must be available to the local as well as the foreign student. It seems inevitable that we shall continue to expand into the tropical areas rich in their natural resources long after the war has finished. If we do then we must accept the public health responsibilities and malaria will always be the foremost in the picture. Actually malaria may be one of the principal determining factors in deciding the failure or success of many of our postwar plans. Certainly we have every reason not to minimize its potential dangers now or at any time in the future.

NUTRITIONAL DISEASES AS A POST-WAR PROBLEM

JOHN B. YOUMANS, M.D.

NASHVILLE, TENN.

The postwar problem of nutritional disease must be considered from two points of view, the general nature and extent of the problem and its scientific and technical aspects. The former will be determined largely by economic social and political factors and is difficult to gauge in advance. The scientific and technical problems can be defined with considerable accuracy.

The general nature and magnitude of the problem will be determined by four factors, first, obviously, the degree and duration of food shortages, second the number of persons affected, third, the level of nutrition which at that time is considered to represent disease and, fourth, the extent to which responsibility for the nutrition of populations is accepted by responsible agencies.

DEGREE AND DURATION OF FOOD SHORTAGE

To some extent the state of food supplies at the end of the war may be forecast by the present situation. Destruction and diversion of food and interference with production transport and distribution have lessened the normal supplies of the world and have caused or are threatening to cause shortages. Even nations which produce surpluses find themselves limited because their products are lent to or seized by others. To offset these unfavorable circumstances, certain measures have been instituted to relieve existing and threatened deficiencies, some of them even before the war began. Increased production is feverishly pushed in many countries, even in those actively engaged in warfare. Various controls, including rationing, not only conserve supplies but equally or more important from the point of view of nutrition promote more uniform and equitable distribution. New and hitherto unexplored sources of food are tapped. The effect of such measures is well illustrated by the notably successful results in England, where increased production, fairly satisfactory rationing and control have contributed greatly to maintain an adequate food supply and lessen the dependence on lend-lease and other imports.

NUMBER OF PERSONS AFFECTED

The situation of the world's food supply has been described by Bennett¹ of the Food Research Institute of Stanford University. It may be summarized according to this author somewhat as follows. In Nazi dominated Europe there is a food stringency which in some places is sufficient to cause nutritional disease. In the large segment under Japanese control, food supplies while they are probably deficient according to proper standards are no worse and possibly are better than before the war. In the United Nations area supplies may be limited in some items but in general are sufficient. These estimates refer of course to gross supplies and do not take into account distribution within populations a problem to be discussed later. Very similar estimates are expressed in more geographic detail in a

Read before the National Conference on Planning for War and Postwar Medical Services, New York, March 18, 1945.
1. Bennett, M. H. The Food of Europe in 1942. *Proceedings of the National Conference on Planning for War and Postwar Medical Services*, New York, March 18, 1945, pp. 1-12.

series of articles in the January issue of the *Annals of the American Academy of Political and Social Science*. Recent estimates by the U. S. Department of Agriculture are that Europe, exclusive of Russia, has suffered a decline of food supplies of only 2 to 3 per cent in the past year.² Personal information from private sources in German occupied territory indicates little change from a year ago. What the situation will be at the end of the war cannot be known at present. It seems safe to assume, however, that large groups of people will not only have an insufficient supply of food but will have been living under such conditions long enough to have developed significant if not gross nutritional deficiency disease.

It is probable that the greater number of these will be in enemy occupied or controlled countries. Depending on the course of the war, the number at the end of the war may be lessened if the policy is adopted of feeding populations as they are liberated. This would decrease the stocks of those countries furnishing the food but in turn would lessen the requirements in the immediate postwar period. At that time suddenly expanded demands may require large supplies and though they may be adequate, all the expanded production will probably be needed to meet them.

LEVEL OF NUTRITION

The third factor determining the size of the postwar nutrition problem is the level of nutrition which is considered as indicative of disease. This is a scientific factor of importance because it forms part of the basis for calculating the degree of deficiency and measuring the amount of relief needed. In practice, however, it is overshadowed by the fourth factor, which is social and economic. This level can be fairly satisfactorily defined much better even than before our entry into the war. One measure is the required daily allowances of the various nutritive factors for which the recommendations of the Food and Nutrition Board of the National Research Council constitute an authoritative and widely adopted standard. Another is the physiologic tests of nutrition which are available for several nutritive factors. What these standards will be at the end of the war is unknown, but the tendency in nutrition at present is to consider levels of nutrition pathologic and constituting disease which in the past would have been accepted as normal, and the discovery of new and more subtle deficiencies and means to detect them suggest that our concept of nutritional disease will be broadened and the size of the problem increased.

RESPONSIBILITY

The fourth factor is the extent to which responsibility for nutrition is accepted by whatever agencies may be concerned. Obviously, this responsibility will extend in various directions. What peoples will it include and how many? What classes in a population? Will it be concerned with all or only special groups? An even more difficult decision as to responsibility remains. For what level of nutrition shall responsibility be accepted? Shall it be only the emergency relief of acute starvation? Shall it be a restoration of nutrition to the level existing before the war in the populations and countries con-

cerned or shall the task be that of establishing and maintaining nutrition at a level which is believed to be desirable by present day standards or those current after the war?

Some intimation may be had from the statements and the announced aims and policies of the heads of governments and of those who may have to do with this postwar problem. These have been well summarized by Bennett.³ Thus, the Atlantic charter implies a freedom from want of food for all men in all lands. Mr. Churchill holds out the hope of food with freedom to the peoples of Europe. Our Secretary of State stresses the need for swift and effective action to meet pressing human needs and the Secretary of Agriculture, Mr. Wickard, warns that to have a stable peace there cannot be widespread starvation in some parts of the world with surpluses in others. Free governments of conquered countries of Europe have announced the intention of securing food for postwar needs in liberated countries. Recently a director of foreign relief and rehabilitation for the United States has been appointed. Rehabilitation and relief must include food and nutrition. As Bennett has said, "The idea of providing adequate diets for all seems in the air." Finally, the recent plans of the National Resources Planning Board, as announced by President Roosevelt, leave no doubt of their intentions with respect to this country. A full and adequate nutrition for every one is the declared intention. It is apparent that, if responsibility is accepted to the extent which is implied, the task will be stupendous even for this country alone. It must in fact become a plan for the more distant future as well as for the immediate postwar period.

TECHNICAL AND MEDICAL ASPECT

Compared to the social and economic aspects, the technical and medical part of the problem is quite easily determined. First there is the procedure of measuring the deficiency, an assessment of the nutrition of any group which may be concerned. Such an assessment will determine the kind of deficiencies, their severity and the number of persons affected, not only for the population generally, but especially for the various classes of the population. While it might be possible simply to provide enough food of all kinds so that everybody or nearly everybody has enough, such a method is inefficient and wasteful. This is particularly true when large supplies of food must be transported long distances and distributed to large populations whose needs may vary in amount and kind. Therefore an assessment is needed. On such an assessment will be based not only the definition of needs but the proper application of relief, and such an assessment will be needed whether one is dealing with a short time relief problem or a permanent plan of nutrition betterment.

There exists at the present time procedures for the assessment of the nutrition of populations and individuals much superior to those of even a few years ago. These are physiologic tests which are capable, in some instances, of detecting and measuring slight deficiencies. However, much improvement is needed and one of the problems facing us is the development of additional and improved tests for the detection and measurement of slight deficiencies.

REQUIREMENTS

The problem having been defined on the basis of nutritional status and need and the degree of responsibility, the requirements for either temporary relief or a long time program of improvement can be deter-

mined quite accurately. As far as immediate relief of the actual deficiency is concerned this can be accomplished quite easily and quickly provided supplies are available as far as adults are concerned. While time is needed for the repair of certain structural defects and in some instances, severe peripheral neuritis of thiamine deficiency for example, complete recovery may never occur in most instances the actual deficit can be made up quickly and body stores returned to normal. In all except very severe deficiency states this will promptly restore function and structure to an approximately normal state leaving complete restoration to follow at some later time. It is necessary however that adequate maintenance supplies be provided to prevent a relapse and insure complete recovery and this becomes of paramount importance for children if a permanent effect is to be prevented or lessened. There is thus introduced an important time-quantity factor. Small amounts of necessary food factors may cure nutritional disease slowly. Still smaller amounts may relieve but never cure. Unless restoration of body stores is accomplished, daily requirements may prevent the accumulation at any time of an amount large enough to relieve the deficiency. Only amounts large enough to restore body supplies to normal and meet current requirements will cause prompt relief and complete cure.

For many reasons it might be advisable to relieve the immediate deficiency of a population quickly by the administration of relatively large amounts of the necessary factors in concentrated form. Ease of distribution, advantages in transportation, great savings in time and personnel and a simpler administration could be gained by such a procedure. No such measures should be undertaken however except for immediate and temporary relief and with the expectation that supplies of food would replace such artificial methods.

For efficient and economical relief and correction of nutritional disease, such measures as are adopted should be varied according to needs as determined by an assessment of nutrition. For some individuals adequate supplies of usual foods may be all that is needed to cure their nutritional disease quickly. Others may require special treatment including hospitalization, the use of special food, vitamin products and the like.

One problem in emergency relief is the effect of increased supplies of one or two dietary essentials on the needs and requirements for others. A good example is the increased need for thiamine as caloric intakes are increased. Any increase in calories would increase the requirements for thiamine, and unless provided in a way which would carry with them increased thiamine might precipitate a deficiency of the latter. In the relief of deficiencies and nutritional disease therefore this phenomenon must be kept in mind and possible ill effects avoided. This is particularly important when attention is directed in the main to one or two nutritional deficiencies and treatment is by means of artificial preparations or special concentrates of food factors unsupported by an adequate general diet.

LONG RANGE PROGRAM

The problem of a long range program of nutritional betterment is much more complex than that of emergency relief. For simplicity I shall confine my remarks to the situation in this country with the understanding that they will apply to others with such modifications as may result from the social and economic factors I have mentioned.

To me it appears unlikely that any significant amount of serious nutritional disease will appear in this country as a result of the war. Rather it is probable that increased public interest, a better distribution of essential food among the various classes of the population through governmental control, rationing and increased purchasing power and the adoption of certain public policies in relation to food supplies and production will result in an even better state of nutrition in general than existed before the war. Such certainly seems to be the situation so far in England, where certain definite gains in nutrition of the general population seem to have been secured because of the war and despite the difficulties caused by the war. The problem will be to secure the potentially tremendous improvement over present day levels of national nutrition. What this level is no one can say accurately. Many statements and estimates are current, most of which are meaningless because they are not based on sufficient evidence or because they fail to take into account all the various factors concerned in the interpretation of assessments of nutrition. Nevertheless there are sufficient reliable studies to indicate that there is a large amount of nutritional disease in this country on the basis of standards now generally accepted. It is thus possible to secure a tremendous improvement in health. Medically it would mean the end of nutritional disease except for sporadic instances of conditioned deficiency. The gain in public health, vigor and accomplishment is difficult to estimate but would be great.

However, to attain the goal in nutrition which has been suggested will not be easy. To begin with public interest in nutrition may lag after the war without the striking reminder of severe deficiencies. The less dramatic gain in health as nutrition approaches the optimum will not be so apparent. Continued effort at public education must be maintained but the mistake must not be made of exaggerating nutrition. Other causes for ill health exist and attempts to make adequate nutrition a panacea will fail as do all panaceas. Also as Mead⁴ has stressed care must be taken in invoking the moral element in relation to food habits which in themselves constitute an important factor in nutrition. For the most part however, the postwar problems will be problems of opportunity. There will be required first of all a much greater production of food. There is every reason to believe that this will exist at the end of the war. Much of this increased production may be needed in the early postwar period for supplying those populations whose production and supplies have been deficient. With peace however production should be increased in those regions also and cooperative effort for this purpose is already planned by the United Nations.⁵ All this increase will be needed however if the goals of nutrition which have been set are reached. It has been estimated that even in this country it would be necessary to increase production of the more expensive foods 15 to 100 per cent to raise the dietary level of the poorest to standards of those who are even moderately well fed.⁶ It thus applies throughout the world the effect on world trade, commerce and industry is obvious.

⁶ Bureau of Food and Nutrition. The Food of the World. 1943.
⁷ International Commission on Nutrition. The Food of the World. 1943.
⁸ U. S. Department of Agriculture. The Food of the World. 1943.

In addition to the production of increased amounts of food there is the problem of increasing the nutritive qualities of foods. Opportunities in this field are many, as is indicated by one example. Studies by the Department of Agriculture Regional Vegetable Breeding Laboratory at Charleston, S. C. showed a variation in the ascorbic acid of thirty-three varieties of tomatoes from 22 mg. per hundred grams to 10 mg. or less than half as much. Similar differences exist on a regional basis and for other foodstuffs and other nutritive factors.

With the great increase in food production goes the problem of food storage, preservation, processing and preparation. Equally great opportunities exist in the problems of preserving the nutritive qualities of food during its progress from production to ultimate consumption. Truly great losses occur in that process at present, and a solution for this problem will go far to ensuring an improved nutrition. A case in point is again vitamin C, an adequate intake as represented by the supply in the food in the original condition often fading to the point of a deficiency before consumption. One way to obviate such losses is, of course, to increase the original content as described, but this is wasteful and a more desirable procedure is improvement in the technology of food handling and processing and in the relatively simple measures of cooking and preserving.

Despite a great increase in production, however, there remains the problem of distribution. Not distribution in the physical sense of transport but equitable distribution among all classes of the population based on need. This problem is almost altogether a social and economic one, all the various aspects of which cannot be touched on here. It does have, however, scientific and technical nutrition aspects because of the methods which may be devised to solve it. It is possible that in the desire to extend the benefits of good nutrition widely and quickly artificial means may be adopted for providing some elements of nutrition which are difficult or costly to obtain in natural ways through adequate amounts of proper food. There are, for example, the procedures of enrichment and fortification of food or food products whose general nutritive standing does not warrant them. In the same category can be placed the indiscriminate use of vitamins and vitamin concentrates by the general public and certain legal restraints, limitations and restrictions which may hinder as well as help good public nutrition. It would be very unfortunate in my opinion if they prevented or retarded progress in securing better nutrition with natural foodstuffs through the process of education and of technological and scientific development.

INDIVIDUAL NUTRITION

There remains to be considered the problem of individual nutrition, the study of which will remain the principal source of fundamental advance in this field. Although gross nutritional disease may cease to be a significant problem except for sporadic and conditioned deficiencies, the prevention of the latter as a complication of other disease is a very large problem. There will also be the influence of minimal nutritional disease on general health. New procedures for determining their effect and detecting their presence must be devised. The improved nutrition of the child will introduce new problems of demand and requirement

which must be studied. Although reliable evidence of the specific influence of nutritional deficiencies on other disease has been meager, newer studies on the relation of nutrition to cellular and humoral immunity make this a promising field for investigation. Similarly the relation of nutritive factors to the intimate details of metabolic and detoxification mechanisms are of particular importance in relation to various occupational exposures and the course and outcome of other disease.

In closing, it may be pointed out that the problem of nutritional disease is much like the problem of syphilis. Both can be eradicated or nearly eradicated. Scientifically the means are quite simple and quite clearly defined. It cannot be accomplished, however, without the cooperation of many agencies, scientific, medical and social, working together on an adequate plan with vision and with courage.

DISCUSSION

DR. C. G. KING, Scientific Director of the Nutrition Foundation, New York. The social and economic factors are more staggering as we approach them at present than the purely scientific factors. First, we should recognize as a nation that we do not have true food surpluses in the proper sense of the word if we are speaking in terms of the problem of adequate nutrition for our entire population. We have wrong balances, we have deficiencies of the commodities most needed, we have surpluses of other commodities. We surely do need long range planning and approach not only in our own nation but to the worldwide problems in nutrition. How much of our nutritional problem is properly classified as nutritional disease? It seems to me more broadly a problem of nutrition. When we get into the area of the degree of malnutrition that is most prevalent in America, there can clearly be a question of definition, of whether or not it is disease.

I should like, in the next few moments of my discussion, to cite the significance of approaching the overall community problem of nutrition. We have Sir John Orr's report that in Scotland, in the midst of the war upheaval, they were able to lower their infant death rate to 20 per cent below the prewar level, even though it had been rising steadily up to the beginning of the nutrition program in 1941. We have the report of Ebbs, Tisdall and their associates of Toronto of the great improvement in the health of infants and mothers by rather simple improvements in their food supplies. We have the reports of Dr. Hazel K. Stiebeling and her associates in the Department of Agriculture indicating that approximately half of our American population is distinctly below a level that would be accepted as satisfactory in their nutritional provision. We have the concept of nutrition and malnutrition presented by Dr. Kruse, which brings in the question of time and intensity and I think really opens up a somewhat new era in the whole approach to malnutrition.

Basically, I think that most lacking in the entire picture is the provision of clear, convincing evidence to the medical profession that the nutrition problem is one of major importance in terms of health. We have a lot of these reports based on limited surveys and studies, but I have a feeling that many of the men who are leaders in the medical education field especially still have a lot of reservation of just how significant in terms of public health is this problem of nutrition. We might approach it from the point of view of the relation that nutrition has to such widespread prevalence of dental caries, to the widespread prevalence of impaired eye function, faulty eye structures, to the neurologic disturbances which have in the past been so often attributed to alcoholism, strain and other stresses other than nutrition.

We have a great opportunity ahead if we can combine the point of view and the information that the research people, working in the laboratories with experimental animals, have in their attitude toward the problem of feeding animals for their best health with the point of view taught in approaching the problem of public health in our schools of medicine. I think

7 Auchter, Eugene C. Nutrition Begins with the Soil, The Food Front, A Series of Eleven Lectures delivered in the U. S. Dept. of Agriculture Auditorium, March 11 April 15, 1942, Washington, Government Printing Office, 1942.

it is a very fine thing that we have centers growing such as Dr Youmans is building at Vanderbilt and Dr Stare is building at Harvard Medical School. Out of those centers there should come an adequate training and appreciation of the human problems in nutrition analogous to the problems that the men in the laboratory have been developing over the past twenty years.

As specific indications of this carry-over, I think almost all biochemists have been impressed within the last two months with the work in Dr Rose's laboratory at Illinois and Dr du Vigneaud's laboratory here in Cornell Medical College showing that within twenty-four hours disturbances in the body's handling of protein can be severe by omission of only one amino acid. Within twenty-four hours Dr Rose then put his patients back into a positive nitrogen balance from a previously established negative nitrogen balance by changing only a few grams of one amino acid. The rapidity with which those swings take place, it seems to me, would impress any one interested in normal human physiology. What significance it may have in health is indicated, I think, in a preliminary way by Dr du Vigneaud's studies of methionine as one typical amino acid which greatly affects the function of such organs as the liver, kidney and muscles.

We need a worldwide approach to the problem because, as Dr Boudreau has so well pointed out, the stability and health of every population in the world is a matter of major concern to all other areas and populations in the world. The Nutrition Foundation was set up by the food industry to support primarily basic, fundamental research in nutrition, but they have another aspect of their program in promoting good sound education relative to nutrition. They have a determination to work, to see that the food supply at least can make its best contribution to public health.

THE SUPPLY OF DRUGS AND MEDICAL MATERIALS IN THE POST-WAR PERIOD

COLONEL CHARLES F. SHOOK
MEDICAL CORPS, UNITED STATES ARMY

While our military, naval and marine forces are still facing the common enemy and while our merchant marine is still struggling against the hazards of the sea it is not only fitting but appropriate that industrial and professional leadership should gather for a review of its prospects and responsibilities.

War production is our present paramount duty and will remain so until the war ends. Nevertheless there is a future, that postwar period of adjustment which should be of vital importance to us today.

My subject, "The Supply of Drugs and Medical Materials in the Postwar Period," should be expanded to include all supplies and equipment essential to the maintenance of health. Many believe that postwar planning is premature. In fact, there are many who contend that the mere thought of peace problems now is a waste of mental energy. It is questionable whether the serious thinker will agree.

One of the precepts of the Army has been "In time of peace prepare for war." How well this has been accomplished has been demonstrated in every major war involving our nation. The Army, augmented by its civilian components has with the least practicable delay mobilized its manpower and its resources and proceeded to the task of defeating the common enemy in the quickest yet most economical manner. By that I do not mean cost in money but rather in the expen-

diture of critical manpower and materials. Such successful accomplishments could be made possible only by continued study into possibilities and the completion of plans of action. Success in any endeavor can never be accomplished without planning. Every one knows that the war is far from won. Our war budget should dispel all doubt on that point. Nevertheless it should therefore fall in line. "In time of war prepare for peace."

With the continued success of our allies, we Americans are becoming optimistic as to the future. The defeat of our common enemy appears more and more certain. Maybe not this year or even next, but our confidence has risen and we are positive as to the ultimate decision. Our many columnists, writers, economists and business executives, realizing the necessity for future planning, have begun to discuss postwar conditions. Experience is being brought out of the deep dark recesses of the past, and consideration for the future is coming to the front.

Our President has visualized this need as demonstrated in his establishment of the National Resources Board and the Defense Supplies Corporation. The former is charged not only with the husbanding of our resources but the proper utilization of them after the termination of hostilities. The Defense Supplies Corporation likewise protects our future by building stockpiles of critical materials and controlling their distribution to essential needs only.

As far as postwar planning is concerned, our Congress is naturally more interested in the international situation than domestic planning at this time.

AFTER THE FIRST WORLD WAR

Planning is dreaming, and any plan of action devised is influenced to a great extent by the personal element of the planner. Before any plan can be recommended for future action, it is best that the subject be developed by a description of the postwar period of World War I and its effect on the various industries involved in the production of health supplies.

With the sudden termination of hostilities on Nov. 11, 1918 our government was confronted with one of its greatest economic problems. Industry was keyed to its maximum production, and vast quantities of supplies of all types and descriptions were in our warehouses, en route overseas, in the hands of our troops in France or awaiting shipment from the factory. With the cessation of hostilities we no longer required actual munitions of war or to a lesser extent large quantities of maintenance and operational supplies. This flow of supplies was so well organized that its momentum could not stop over night.

Each and every plant had its problems and difficulties and each and every type of commodity had its peculiarities. Some types of production were still required in large quantities for the operation of our peacetime army. By and large however, we had on hand, either in the United States or on the soils of our allies, millions of dollars' worth of supplies and equipment, soon to be declared as surplus.

Then, as today we had facing us the rehabilitation of most of Europe and to some extent the countries of our former enemies. The care of the sick and the wounded and the utilization of medical supplies and services acknowledge no race or creed. Humanity must be served and we in a grandiose yet probably not in such a controlled or planned manner turned over to our surplus supplies that were over-eas to a rehabilitation

program. Mr. Herbert Hoover, who had been in charge of the Belgian Relief from the time of the invasion, wisely distributed many medical supplies in such countries as were believed worthy of assistance. At that time there were transferred to the American Red Cross approximately \$10,000,000 worth of drugs, surgical dressings and other surplus supplies. Much of the material was required for the continued maintenance of our army of occupation, but a lot of it, sold in France to the French government, did find itself entering the channel of international business and competing against the patriotic industry which had produced it under the hardships of expansion, depleted manpower or material handicaps. Those stores in England were purchased by the British government. I can find no record of these goods returning to the United States. A moderate amount of medical supplies was sold to Poland, Greece, Serbia and the newly created countries of the Ukraine. Only a small quantity of technical equipment was returned, owing to cost of transportation.

Those stocks still in the hands of the manufacturer, either completed or in the various steps of fabrication, were in many instances either taken over by the government as such or retained by the producer.

Large stocks were accumulated and transferred to the Surplus Products Board, by which they were sold in job lots to the highest bidder, sometimes by direct sale and sometimes by auction. Warehousing was expensive, and the government was more than anxious to rid itself of this impediment. We still see evidences of our excess stocks of World War I in our many army and navy stores, where everything formerly used in the service can be procured for camping, hunting and other outdoor sports.

It has been stated that pushcarts on lower Broadway sold ointments in penny sales. (I question that the Food and Drug Administration would permit a repetition of this action.) Surgical scissors and even certain surgical instruments found their way to the general merchandise counter. Equipment passed through numerous hands to many various terminal positions.

With the advent of 1939-1943, stocks of World War materials began appearing over the country and at last the investor realized a possible market for his frozen asset, either through lend-lease or through the depleted civilian market.

Dressings, surgical instruments, including dies, jigs and forgings, field equipment and other nondeteriorating materials were made available. Some of the surgical instruments made an appreciable assistance to our allies under lend-lease.

With the return to the market of such large quantities of finished products the manufacturer began to feel its effect. Production lagged, world markets went to other countries because of lower labor costs. Only the hardiest of manufacturers were able to withstand all these reverses. Many good reliable concerns either closed their doors or came close to it with the usual attendant financial loss.

These conditions cannot be permitted to arise another time. Now that the various health supplies industries have expanded far and beyond their peacetime requirements, it is to their benefit if they start now to plan their postwar possibilities: new markets, new products, yes and even many new sources of supply with the continuation of new products encouraged by a wartime condition.

PRODUCTION FOR THE PRESENT WAR

The expansion of production from 1939 to 1943 has been quite exceptional. To meet the present war effort it was necessary that industry expand its production manifold. Production status depends on the law of supply and demand, the restrictions placed on production by the War Production Board and the availability of material and manpower. It has been said that the Army has overbought. Perhaps that is true in a few commodities where past experience was lacking and estimates of requirements had to be based on knowledge of similar items. Perhaps certain stocks are in excess, but remember, we have not as yet gone into an extensive fighting war where stocks are depleted over night. It is much better to have overprocured and be ready than to have an empty ladder in time of actual need. This war is not like its predecessor. Then we had but one front. Today we have nearly forty fronts and each must have its "pipeline" of supply filled.

Some industries required little or no expansion to care for the growing needs of our military and naval forces as well as our allies. Chief among these may be listed pharmaceuticals. Perhaps a tablet machine or an ointment mill has been added and perhaps a second shift has been required, but on the whole the pharmaceutical industry was able to cope with all our requirements and complete its deliveries in a satisfactory manner without appreciable expansion. The same may be said of several other industries allied to health supplies. There were, however, many instances in which expansion either in whole or in part was 200 to 300 per cent and even 500 per cent. True, the latter is the exception rather than the rule and involved materials or equipment either new to production or especially peculiar to warfare. These would include the expansion of such chemicals as the sulfonamide compounds, atabrine and essential vitamins, together with surgical instruments, diagnostic instruments, sterilizers and X-ray machines.

POSTWAR PRODUCTION

On the termination of hostilities, industry geared to a maximum production will not materially slow down its machine but will continue for some time.

Where will postwar production be required?

1 The equipping of educational institutions whose supplies and equipment have been materially curtailed during the emergency.

2 The replenishment of depleted retail stocks as well as an established inventory in the wholesalers' warehouses.

3 A return to the normal type of fabrication and the discontinuance of makeshift and substitute production.

4 Increased sales to professional men leaving the services and returning to civilian practice. In a recent poll by *Fortune*, 55 per cent of business executives anticipate a greater volume of business than even 1939.

5 The completion of hospital projects and the replacement of worn out or obsolete equipment. This phase will by no means be a minor one. Our hospitals have shown their patriotism through the continued usage of old unsatisfactory equipment and the practicing of rigid economy. Their financial balance is probably the best in history, and it will be their first desire to invest in durable goods.

6 Proper and supervised utilization in the hospitalization program of our Veterans Administration, the equipment going into a hospital program and the main-

tenance supplies over a general distribution. This procedure was used after World War I.

7 It can be visualized also that an organization similar to the Civilian Conservation Corps may be established to care for discharged soldiers needing positions training or even rehabilitation. The CCC required hospitals and dispensaries, which means supplies and equipment.

8 Stocks in the territorial limits of the United States would be available for transfer to other government agencies, the American Red Cross, the rehabilitation program and certain nonprofit operated hospital groups. Also the stock level of supplies in established army hospitals and dispensaries could be raised.

CONCLUSIONS AND RECOMMENDATIONS

In the transition from war to a peace economy there are certain conclusions and recommendations to be made.

1 An act by Congress or a ruling by the President under his War Powers Act that manufacturers who filled government contracts should be permitted to repurchase any surplus materials remaining in the hands of the government after the cessation of hostilities.

2 The suggestion to Congress that an appropriate war reserve of nondeteriorating supplies and equipment be stored for future eventualities whether they are for war, flood, fire or other disasters. We should never again deplete our war reserves.

3 From 1924 to 1941 the War and Navy Departments operated what was known as a procurement planning division. Their plans were laid to determine what would be wanted in time of emergency, how much would be required and where it was to be obtained. A similar setup is recommended to any individual or group of individuals charged with the rehabilitation program. Time is essential here. The personnel to be chosen is important, but the prime factor is the proper recognition of health supplies and industries involved. We know the countries we must aid and we know the type of materials they will require but have we any idea as to quantity? I question that any answer is available at this time.

4 There will undoubtedly be a recession in prices after the war. The retailer should be encouraged to watch his stock and not overload. Better and more substantial products will soon be on the market at better prices. Good business will watch the market closely. A price protection legislation will be as essential after the war as now, probably in the form of duty on exports.

5 The various industries involved in the manufacture of health supplies should become realistic. While many concerns have already set up postwar planning boards, all facilities should begin to study their future status in a community suddenly removed from wartime production. Research should be geared to new products, new markets both domestic and foreign and new fields of production.

6 On the termination of hostilities, surplus stocks of maintenance supplies will immediately become evident. This is not true of equipment. Our hospitals and dispensaries will be required until after the Army has been demobilized to its authorized peacetime status. If history repeats itself, such equipment will not be declared surplus for about two years. This period should be carefully studied and steps taken to alleviate the effect on industry.

7 I cannot encourage my next recommendation too emphatically. That is the continued use of industry advisory committees to advise and assist the various

government agencies in the timely and judicious handling of surplus stocks of medical supplies. A special subcommittee should be formed for just such a purpose.

In closing, let me reiterate, planning at this time for the postwar period is essential and proper planning will avoid many of the difficulties evidenced after World War I. There will be ample medical supplies and equipment available for the rehabilitation program with the possible exception of biologic products, vitamins and certain pharmaceuticals required in the treatment of diseases peculiar to a particular foreign country. To assure further the availability of supplies required overseas it will be necessary that industry have at least an idea whether or not its products will be required in such program. With proper supervision and control of our medical supplies on the termination of hostilities I cannot visualize any great interference with our economic setup.

DISCUSSION

LIEUT. COL. H. F. CURRIE. In his presentation Colonel Shook mentioned one factor in the channeling of drugs and medical supplies that has been of great interest to me, and one which I think should be given further consideration—rehabilitation. The present war is unusual in that more people are involved than ever before and destruction of materiel and humanity is shocking in its magnitude. Immediately after fighting ceases, our nation will be faced with a dual responsibility: first, Europe, North Africa and the Japanese controlled countries must be policed to prevent a reactionary crime wave and violence because of hunger and unrest. Second we must initiate, supervise and supply needed material for the rehabilitation of those nations whose level of civilization has been lowered by the Axis. In this we can be defeated by two factors: hunger and disease. Large quantities of drugs and medical supplies will be needed. The policing of the aforementioned countries with widely dispersed naval and military units will require many medical installations and frequent replenishment of their medical supplies. This will utilize stocks of supplies then on hand. More important, however, adequate medical care must be established in the countries now being dominated by the Axis forces and this will call for large stocks of drugs and medical supplies.

Because our present production of these supplies is regulated by a carefully planned army supply program, projecting the monthly need of medical supplies through 1943 and 1944 there is less likelihood of a tremendous surplus of supplies than after World War I.

The second problem, medical supplies for the purpose of rehabilitation, affords an opportunity for our nation to render a great service to humanity and at the same time assist our drug and medical industry in maintaining a constant rate of production during the postwar period. This can be done by utilizing the excess production made available by decreasing army and navy requirements. Immediately after the war military requirements for production will be sharply decreased. Plans must now be made for conversion of this excess capacity of the drug and medical industry to the needs of our rehabilitation program which will continue for years, thus allowing a gradual transition from war production to peacetime production. Such a program must be instituted immediately and must be guided by persons who know the industry who are familiar with procurement of medical supplies and above all who have a broad and sympathetic knowledge of the problem facing us in the postwar period. Such action will be of material aid in maintaining a sound economic structure in our drug and medical industry and if properly planned and applied the production of drugs and medical supplies will continue at a fairly uninterrupted pace on the cessation of hostilities.

In conclusion let me impress on you the fact that the present war is far from won. We have a hard fight ahead of us. If our drug and surgical industry first consideration must be to give our fighting forces all they need for victory. If we win there will be no need for postwar planning.

MAJOR HOWARD F. BAIR I take it that Colonel Shook's paper is more directly aimed at industry than it is at medical service in general and I know because I have heard some of you express yourselves to that effect, that many of you in the audience, representing industry, are concerned with what will happen to the enormous quantities of materials which the government is today purchasing. I think it is only natural that you should be concerned because the quantities in many ways seem fantastic—and yet I for one speaking as a former member of the surgical supply industry, feel that that concern is needless. You have heard several sound recommendations from Colonel Shook as to certain protective safeguards that should be set up for industry and you have heard Colonel Currie say that worldwide rehabilitative necessities will use up these materials. I think it may safely be said that what the industry needs is a constructive, rather than a protective outlook. Right now, sitting here, you are bothered that such large quantities of material will be thrown on the market that your industries will be badly crippled. I believe that fear to be groundless. In the first place, we must all agree with Colonel Currie that there may be no surplus products because of the world's needs. But suppose these things do not come to pass and suppose there are large quantities which the government would decide not to keep but to throw on the market. I submit that even this would not be harmful. Colonel Shook has discussed what happened to surplus materials that were thrown on the market after World War I, but I submit that the greatest growth in the surgical, pharmaceutical and laboratory industries the world has ever seen occurred in this country from 1920 to 1940, in spite of the merchandise which the government sold at auction. Indeed, it would be easy to argue that at least some of the growth occurred because of the goods thrown on the market—but as for that, there is no time. So, I think industry needs to get rid of these fears, first because domestic and worldwide demands will be too great and, second, because large quantities will be kept by the government (as Colonel Shook has indicated) and, third, because even if some substantial proportion should reach the local market, disaster will not result.

There are two other points which Colonel Shook has made, which I think worthy of elaboration. He has indicated that price control legislation will be as essential after the war as now. If he will allow me to disagree, I hope that will not come to pass. To begin with, there is no actual price control legislation in this country other than price ceilings and the fair trade laws permitting the manufacturer to set his own resale price. Any further extension of price control legislation, particularly in this field, would be likely to stifle growth. The entire health supply field is expanding. The close of the war will see the industries participating in this conference standing on the threshold of new avenues of exploration and growth. Those who feel that price protection is necessary for the exploration of these avenues do not understand that all economic history has proved that a free market encourages developmental research and improvement.

The last point is this matter of conversion to peacetime production, which Colonel Shook has discussed so elaborately. In this connection there is one point which seems to me is well worth making. He has indicated that some of your industries required little or no expansion to convert to war. True, he has said that others have had to expand as much as 500 per cent, but he has further indicated that on the termination of hostilities it will not be necessary for industries materially to slow down. I wonder if we all realize how different your situation is from most others. Ordnance, aviation and shipbuilding to a large extent were created out of thin air. A great many war industries are producing not wealth but engines to destroy wealth. When the war stops they must cease operations nearly 100 per cent. The wealth of our country lies in our ability to produce material useful for peacetime better living. If our industries here assembled have expanded, then so much the better—for you have expanded for the production of wealth creating materials, not for the production of destruction and debt.

No one can foresee the shape of things to come, none of us can see what economic patterns our country will adopt in the postwar period, but we do know that a large part of our population, and a much greater part of all the populations of the

world, have been underprivileged healthwise, and so it would seem very ill chosen pessimism, indeed, to worry because your industries may be geared up too heavily for our present horizons. I, for one, have no doubt that we shall see many new horizons before we are much older.

COL. C. F. SHOOK I think I should like to clear up one thing, and that is some control over supplies. After the last war, if I am not mistaken, and I think most of the surgical instrument people will agree with me, there were great inroads of German instruments into this country as the result of cheap labor. The German government gave a bonus or wrote off certain amounts of money so that they could compete with our duty. That is what I was referring to in financial regulation. I believe that, as our present laws stand, anything manufactured in the United States can come back duty free. We don't want to see those instruments, as in the last war, where we paid \$175 for an operating case come back and be sold for \$17 and then go out on the market for \$50. But it did happen in the last war.

POSTWAR NEEDS FOR MEDICAL AND OTHER TRAINED PERSONNEL

EDWARD C. ELLIOTT, LL.D.

President, Purdue University, Chief, Professional and Technical
Service, War Manpower Commission

WASHINGTON, D. C.

I am not a physician and therefore, here in the presence of physicians must speak with humility and with a certain self-protective caution.

I am not a prophet and therefore may not presume to lift the curtain of time that separates the world of the present from the world of the future.

I am not a protagonist and therefore possess but little of the crusader's zeal for the winning of followers of ideas fashioned to save either a part or the whole of mankind.

I am not a member of the immediate family of Pollyanna and therefore am not exposed to the hazard of a soft optimism.

I am not a pessimist and therefore am not armored against a dynamic faith in the intelligence and disposition of men to proceed promptly to salvage good from the evil and destructive days in which we are.

I am, however, commissioned to represent in this place the professions of learning the preparation for which requires time and talent and tasks of those who would learn for a purpose. This commission obligates me to serve as a coordinator of the physician, the prophet, the protagonist, the family of Pollyanna, the pessimist and, perchance, the patriot. Not, let it be hoped, that sort of coordinator who, according to one of my waggish Washington associates, merely transforms "organized chaos into regimented confusion."

SIGNIFICANT TRENDS

These whimsical reflections do not divert me from the discouraging observation that there are too many ifs and whens and hows and whys and wherefores as to both the present and the future to permit either logical or acceptable answers to the several obvious questions raised by the particular title which this conference has assigned to me. A multitude of uncertainties and variables of ever changing force must be dealt with. Most of all there must be a constant awareness of the gravest of risks, that is, the current tendency to oversimplify the solution of the difficult war problems of the realistic today and yet more difficult postwar problems of the indefinitely remote tomorrow. It is

Read before the National Conference on Planning for War and Postwar Medical Services, New York, March 15, 1943.

altogether too easy to reach conclusions compounded of hopes and speculations, seasoned with a mere sprinkling of facts, instead of following the trail of clear facts, trusting that these do not lead to a point too far from our chosen goals

Within the prescribed limits of twenty minutes it is impossible to do more than to "spot" for each of the two phases of the trained personnel problem—the "medical" and the "other"—certain of the trends and facts of today that appear to have significance for the postwar period

NEED FOR MEDICAL PERSONNEL

The first half of the subject matter suggested by the title directs us to the postwar needs for medical personnel. You will receive my forecasts as the products of the observations of a mere layman. While they may not run easily in the time worn ruts of the profession of medicine, they do represent serious meditation on matters of far reaching concern to the ways of life of a people who instinctively know that nature has written important sections of their charter of liberty. And nature demands that they have care for what nature has given.

It seems self evident that the postwar needs of medical personnel will be determined principally by

- 1 The length of the war
- 2 The number of the wounded and permanently disabled returned from the battle fronts
- 3 The extent of the casualties of medical men serving with the armed forces
- 4 The nature and amount of the accumulated effects of the reduction of medical service for the civilian population during the continuance of the war
- 5 The available supply of the newly trained personnel coming from the medical schools during the period of the war and after
- 6 The social philosophy adopted for the utilization of medical services in the interest of national health

Under the most favorable circumstances as to the duration of the war, the number of casualties and the efforts to speed up the training of both men and women with the minimum qualifications for the practice of medicine, we shall find that there are too few doctors to serve our needs even when these needs are measured in terms of the pre-Pearl Harbor days rather than those represented by the demands for the hospitalization and rehabilitation of the wounded in battle and by such proposals for enlarged medical service to the American people as those announced last week by the National Resources Planning Board. The statement "It is essential that public provision be made for meeting the needs of our people for more adequate medical care. Toward this end the federal government should stimulate, assist or undertake constructive action to provide such care for the millions of our people whose need cannot be fully met from their own resources" will provoke many a sharp controversy during the days ahead, within and without the profession of medicine. However, the issue may not be brushed aside by those having any part of the responsibility for the leadership of postwar medicine.

UNIVERSAL MILITARY TRAINING

Here I am tempted to digress and to call attention to one possible and entirely new factor that may have a tremendous influence on the amount and character of the postwar needs for medical service. Here I fear I am for the moment assuming the role of a protagonist.

If the nation is sensible in its foresight for the days after the war, adequate provision will be made for what

has come to be called universal military training of our youth. In spite of the idealism with which we are mobilizing and energizing our powers for victory, this idealism must not lead us to any self delusion as to the necessity of guaranteeing the continuance of that victory by a quality and a quantity of trained military power that will not be found in any peace pact.

Each generation of American youth has a right to the opportunity to be prepared for its civic jobs. As human nature is, individually, racially, nationally, defensive war is likely to remain as one of the civic jobs for free men.

If and when we have such a plan for the continuous mobilization and training of American youth, it follows that new and greater drafts will be drawn on the profession and institutions of education of the nation. Thereby the standards of national health, national security and national unity will be established and realized.

EXPANSION OF TRAINING FACILITIES FOR MEDICAL PROFESSION

During the past six or eight months I have had opportunity to know the limitations of our medical resources. Already approximately one third of the medical manpower (dental, one fifth) has been absorbed by the armed forces. As the war continues there is a strong possibility that there will be available to the civilian population not to exceed one half of the peacetime medical services. The pressing question is what are we going to do about it?

It is my seasoned judgment, taking into account the estimated effects of war service on the available supply of medical personnel, the demands for medical service to those returning from the battle fronts, the new standards of medical care for the American people, that the time is already here when serious consideration should be given to plan for the expansion of the training facilities for the medical profession either through the enlargement of the capacity of existing institutions or by the creation of additional institutions.

One further item must be included in the inventory of postwar medical problems. This is the recruitment and development of young men and women possessing those rare qualities essential for medical research. Of the many disastrous permanent losses of the war, that of the diversion and thwarting of scientific abilities of the oncoming generation may not be discounted.

OTHER TRAINED PERSONNEL

The present assignment includes not only medical but also other trained personnel for postwar needs. Consequently I now deal briefly with certain other fields the effective occupation and cultivation of which require thorough and more or less prolonged technical preparation. Modern civilization as we have come to know it in this generation and as we are able to foresee it for the coming generation is more and more dependent on people possessed of hopes. But hopes are but thinly insubstantial unless resting on the firm base of health and highly trained skills with which to participate in productive work and to share in its rewards.

The war has transformed this country into a great training school. All over the land are to be found training centers for the Army, the Navy, the Air Force and the collateral services. The great war industries acting independently or in cooperation with government agencies, have instituted programs for the teaching of unnumbered thousands of men and women their small specialized part of the business of making the machine-

of war. As an illustration of this the work of the Engineering, Science, Management War Training Program of the Office of Education may be cited. In the past two years over 900,000 men and women have received training in the fields of engineering, physics, chemistry and production supervision. The report for November 1942 shows that 156,000 students were in these special war courses for that month.

The Army, the Navy, the Air Corps and other branches of the armed services are today in the first stages of one of the greatest of the educational undertakings of the war. Authorizations have been made whereby the armed forces are entering into contracts with nearly five hundred American colleges and universities wherein during the coming year, some three hundred thousand men and women in uniform will receive training essential to fit them to perform the work needed by the armed forces. Including medicine and dentistry the greater part of this training is of a technical nature. The impact of this enterprise on the professions of medicine and dentistry may not be disregarded.

TECHNOLOGICAL TRAINING

During recent decades we had to think ourselves as a people schooled in the ways of science and machinery. Only the inexorable demands of scientific mechanized warfare have convinced us how short we were of scientists and of workers skilled in the designing, making and servicing of the multitude of units of the machines of war. Since 1939 the nation has discovered beneath the peacetime surface of things its tremendous pool of human ability requiring but brief and intensive periods of training for high productive use in the small as well as the large war industries. The unprecedented accomplishments of these industries furnishes convincing testimony that to some degree we as a nation had reached that educational goal described three centuries ago by Milton "to perform skilfully and magnanimously all the duties of peace and of war."

Modern warfare is destruction raised to the *n*th power. This is a bit of tautness. Less trite perhaps to say that, from the point of view of discipline and the development of the productive skills of the nation, the war displays a constructive side. I am persuaded that unless it has a catastrophic duration the war will result in greatly increased attention to matters affecting the vitality and health of our people. Likewise we shall come to see that we cannot afford to neglect the task of training all for a place in the organization for an economic productivity that is technological in nature.

There are many amateur seers today divining the future by gazing into their own private crystal globes. Not a few of these are uttering dire forebodings as to the future of all our technical education as this is affected by the war. Their principal fear is centered in the effect of the streamlining of the established schemes of professional instruction designed to produce not merely trained minds but also educated men. Under the urgencies of the war all importance must be attached to the essentials of needed technical performance. Time is the relentless tyrant during the days of war. A resolution transmitted to me by the Board of Direction of the American Society of Civil Engineers is significant.

That this board recommends to the governmental agencies concerned that provision be made for enrolling and retaining in college a sufficient number of engineering students of superior qualifications under such conditions as will permit them to complete substantially the time proved engineering curricula, to meet the war and postwar needs for recruitment of the engineering profession.

This crucial issue I am not permitted now to argue. I am optimistic enough to believe that all forms of higher professional and technical education are to gain something through their war experiences. The war is compelling us to do more and more with less and less in a shorter and ever shorter time. It is conceivable that in the postwar period we shall discover that under the compulsion of peace we can continue to do more and more with less and less for the greater and ever greater benefit of those who learn that the nation may live.

TRENDS IN SCIENTIFIC RESEARCH

A. R. DOCHEZ, M.D.

Professor of Medical and Surgical Research, Columbia University College of Physicians and Surgeons
NEW YORK

The responsibilities of medicine and the medical sciences in the conduct of warfare are ancient and well known. To many they consist of the measures taken to prevent disease and the proper care of sick and wounded. If however, one contemplates for a moment the vast expansion of the techniques of modern war and the necessity for their use in practically all known parts of the world, the almost indefinite extension of the function of the medical sciences quickly becomes apparent. The modern soldier must be adapted to his task by physical fitness, mental aptitude and endurance. In many instances the physiologic mechanisms of the body are not geared to the unusual stresses imposed. The number and variety of diseases to which he is exposed have greatly increased because of the geographic extension of the areas in which he must serve. Types of war wounds and other injuries are more varied and complicated as a result of the multiplication of the instrumentalities of warfare. In order to foresee and successfully solve the many problems which are arising, a well planned and integrated organization of medical science and practice has been developed.

THE NATIONAL ACADEMY OF SCIENCES

In 1863 Abraham Lincoln provided for the establishment of the National Academy of Sciences. One function of this body of scientific men has been to give advice to the government concerning problems of national importance. In the very beginning of its activities the National Academy of Sciences organized committees to consider and advise in questions of military and naval significance. In time of peace its various activities were continued and extended. In 1916, at the approach of war between the United States and Germany, President Wilson foreseeing the need of a coordinated organization of the scientists of the United States, stimulated the creation of the National Research Council, a quasi governmental body under the general administration of the National Academy and made up of the leading scientists of the nation. During the period of the war the National Research Council was principally concerned with scientific problems related to the prosecution of the war. As with the National Academy, the peacetime value of such an organization quickly became apparent and its activities were extended to the survey and stimulation of research in all the sciences comprised within its field. The range of interest is broad, and numerous committees have been set up whose principal fields of activity lie within the

Read before the National Conference on Planning for War and Post-war Medical Services, New York, March 15, 1943.

mathematical, physical, chemical, mechanical, biologic and social sciences. Of more particular interest to us at the present moment is the Division of Medical Sciences. The immediate concern of this division is problems of medical interest but close cooperation is maintained with all other branches of science.

THE DIVISION OF MEDICAL SCIENCES

At the outbreak of the present world war the Division of Medical Sciences under the chairmanship of Dr. Lewis H. Weed, placed its services at the disposal of the government. Liaison was established with the Offices of the Surgeon Generals of the Army, Navy and Public Health Service and steps were taken to provide advice in matters of current medical practice and to develop research projects in those fields that were urgently in need of further elucidation.

At first the number of problems considered was relatively small but as the immensity of the struggle became clear it was realized that extensive provision should be made to deal with all problems within the whole broad field of medical practice and research. The medical personnel of the entire country was carefully scanned by competent individuals, and groups were selected and organized into committees. These committees are made up of specialists in the many fields of medical science, are equipped to formulate the best medical practice of the day and have the scientific training and knowledge to discern important problems in need of further investigation and to organize the technical procedures necessary to their solution.

At present there function under the auspices of the National Research Council eleven main committees on the following medical subjects: General Medicine, Surgery, Neuropsychiatry, Aviation Medicine, Industrial Medicine, Sanitary Engineering, Shock and Transfusions, Treatment of Gas Casualties, Chemotherapeutic and Other Agents, Drugs and Medical Supplies, and Information. Under these main committees smaller subcommittees have been formed to consider such specific conditions as different types of infectious disease, cardiovascular disorders, problems of nutrition, surgical infections, burns, injuries to blood vessels, nerves and the skeletal system, shock, blood substitutes, psychiatric problems, war neuroses and venereal diseases, also such special problems in aviation medicine as oxygen and anoxia, sudden changes in the forces of gravity, decompression sickness, suitable types of clothing and the medical aspects of a variety of other important questions.

In 1941, while the National Research Council was in process of expanding its organization, the President of the United States established by presidential order the Office of Scientific Research and Development. Previous to this time there was already in existence and in action the National Defense Research Committee comprising a large group of scientists charged with the responsibility of making available scientific knowledge and personnel for the study and development of the instrumentalities of war. The new order added to this group a Committee on Medical Research and brought the two together under a single office. As at present organized, this office has for its director Dr. Vannevar Bush, president of the Carnegie Institution of Washington. It consists of two committees: the National Defense Research Committee under the chairmanship of Dr. James B. Conant, president of Harvard University, and the Committee on Medical Research whose chairman is Dr. A. N. Richards, vice president of the University of Pennsylvania in charge of medical affairs.

The duties of the Office of Scientific Research and Development are to advise the President with regard to the status of scientific and medical research relating to national defense and the measures necessary to assure continued and increasing progress in this field to serve as the center for the mobilization of the scientific personnel and resources of the nation, to coordinate aid and when desirable, supplement the experimental and other scientific and medical research activities relating to national defense carried on by the Departments of War and Navy and other departments and agencies of the federal government, to develop broad and coordinated plans for the conduct of scientific research in the defense program, to review existing scientific research programs, and to advise with respect to the relationship of the proposed activities to the total research program, to initiate and support scientific research on the mechanisms and devices of warfare with the objective of creating, developing and improving instrumentalities, methods and materials required for national defense, to initiate and support scientific research on medical problems affecting the national defense, to initiate and support such scientific and medical research as may be requested by the government of any country whose defense the President deems vital to the defense of the United States and to serve as the central liaison office for the conduct of such scientific and medical research for such countries and to perform such other duties relating to scientific and medical research and development as the President may from time to time assign or delegate to it. A sufficient budget is provided annually for the adequate carrying out of these purposes.

The Committee on Medical Research was charged, under the Presidential order, with the responsibility of making effective those parts of the order relating to medical affairs. Advantage was immediately taken of the existing organization and plans of the National Research Council and the chairmen of the main committees were appointed consultants to the Committee on Medical Research. Existing medical projects were reviewed and plans were made for making the fullest use of the new opportunities for gathering knowledge and initiating research on problems related to the conduct of the war. At present the cooperation of scientific bodies, universities, medical schools, commercial biologic and chemical laboratories and many individuals has been enlisted for the exploration and investigation of the many medical questions arising from the war effort. Problems are formulated by the different committees of the National Research Council, extended and coordinated by the Committee on Medical Research and the aid and suggestion of many individual scientists throughout the country is sought and encouraged. Contracts for the prosecution of the work are entered into with the government and funds are provided for the expenses of the investigation and wherever necessary for the salaries of the scientific workers engaged on the projects. Many scientists are giving a large proportion of their time without remuneration other than the satisfaction that comes from the study and solution of important and interesting medical problems.

At present more than a thousand investigators are giving a part or all of their time to this work and more than three hundred projects have been set up for study.

SOME SPECIFIC PROBLEMS

This large group of medical scientists is well equipped in training, knowledge and experience to investigate and in many instances to solve the physiologic and

medical problems that have developed as a result of the multiplication of techniques and situations of modern warfare. I have already indicated the wide range and variety of investigative problems that must be considered. It would no doubt be of great interest to present in detail the character of the questions to be answered and the progress that already has been made in the direction of their final solution. Unfortunately, sufficient time is not available to cover the entire field and the confidential nature of some of the problems makes public discussion of them inadvisable at the present time. I shall therefore present only briefly some of the more important work that has been undertaken.

All are familiar with the great stimulus that the universality of modern global warfare has given to the development and perfection of the airplane. Among the outstanding achievements of aviation engineers is the development of airplanes capable of attaining great altitudes and of flying at incredible speeds. On the other hand, man is not yet sufficiently adapted to meet the demands made on him by the mechanical genius of the engineer. Stresses are imposed that normal mechanisms cannot sustain. Methods, therefore, must be found to extend the range of adequate function of human physiologic systems.

At an altitude of 12 thousand feet, owing to low barometric pressure, man begins to suffer from an insufficient supply of oxygen and signs of deterioration of physical and mental capacity become manifest. At altitudes of from 25 to 30 thousand feet the oxygen pressure falls to such a low point that life itself becomes impossible. For man to function adequately at such altitudes, increasing amounts of oxygen must be artificially supplied. At 40 thousand feet even the breathing of 100 per cent oxygen fails to meet the needs of the situation. The modern airplane, however, is capable of reaching heights considerably in excess of this level.

Attacking forces in the air reach their goal with great rapidity. Interceptor planes in order to meet this situation must attain altitude in the shortest possible interval of time. Again the genius of the airplane engineer has been equal to the need. The pilot, however, is subjected to a rapid diminution of atmospheric pressure. If the change of pressure is great, decompression sickness, the familiar bends of the deep sea diver, may develop owing to the formation of nitrogen bubbles in the circulating blood. The symptoms vary all the way from local pain to occasional incapacitating paralyzes and deterioration of mental activity.

The speed of the modern airplane is responsible for a variety of sudden changes in the equilibriums of the body. These changes are capable of causing great disturbances of function. When the body is rapidly accelerated it is acted on by a powerful force whose effects are manifested in the different tissues of the body, particularly the soft supporting tissues, the bony tissues, the organs suspended within the body cavity, and the body fluids. As an illustration, sudden change of direction of a fast moving plane, such as occurs in dive bombing, results in increased gravity effects which cause a shift of the position of the fluids within the body, especially the blood. If this shift is toward the trunk and extremities, the blood pressure in the head drops and cerebral anemia results accompanied by diminished visual acuity, the so-called "blackout," and in some instances even by complete unconsciousness.

There are many other problems arising from the needs of aviation medicine. Among the more important are motion sickness with its accompanying nausea and

disturbance of the sense of static equilibrium, and fatigue resulting from observation and bombing flights of long duration. Practical questions of importance have arisen from the necessity of protecting aviators from cold and exposure encountered at extremely high altitudes where outside temperatures may be as low as -50°F .

From this short review one sees that the physiologic capacity of man is stretched beyond its normal limits and must be supplemented in order to meet the strain of modern war in the air.

Much thought has been given to the provision of facilities for meeting these new and complicated situations, and men skilled in the various related fields have been assembled so that the best possible knowledge and ability may be devoted to their investigation. A number of decompression chambers have been constructed and are in operation. The purpose of these chambers is to simulate at ground level the varying conditions to which the aviator is exposed. High altitudes can be achieved in short periods of time and the physiologic effects of rapidly diminishing oxygen pressure can be observed. By means of refrigeration extremely low temperatures are developed. Thus all the conditions that surround the flier can be exactly imitated and functional inadequacies precisely measured. Investigative groups assigned to work with these chambers consist of physiologists, chemists, physicists, physicians and engineers. Provision is thus made for the adequate study of the functional changes that result from oxygen want, rapid decompression, exposure to extremely low temperatures and all other aspects of altitude tolerance. The final purpose of these studies is the discovery of reliable means of supplementing deficiencies and counteracting untoward effects. In like manner mechanical devices have been arranged and personnel provided for the study and remedy of physical disabilities induced by sudden increases in gravity effects, by motion sickness and by prolonged exposure to low temperatures and fatigue.

Perhaps the most immediate danger to which the soldier is exposed is that of being injured in battle. The common types of injury are wounds, contusions, fractures and burns. Such injuries may involve any part of the body and may be single or multiple in character. Body cavities may be penetrated by bullets, shell and bomb fragments, destructive injuries to the central nervous system and peripheral nerves are not uncommon, and important blood vessels may be severed with the resulting danger of gangrene of the affected part. Burns of severe character are important features of modern mechanical warfare. Injuries of all these types are not uncommon occurrences in civilian life, and surgeons are continuously working on the perfection of methods for their care. In time of war, however, such injuries acquire especial importance and an unusual effort must be made to develop suitable and improved methods of treatment. Special studies have been inaugurated in each of the surgical fields mentioned.

In past wars uncontrollable bacterial infection of wounds has always been the principal cause of death. In recent years chemical and biologic agents have been brought to a high degree of usefulness in the control of such infection. The occurrence of tetanus has been diminished almost to the point of disappearance by prophylactic immunization of troops against this disease.

In order to study infection of wounds, special units have been set up in a number of large hospitals of the

country. Their purpose is to test the best methods of using the sulfonamide drugs and other chemotherapeutic agents. Ordinary civilian casualties are used in this investigation. These units are staffed by a variety of specialists, and careful bacteriologic records are kept for the purpose of noting the presence or absence of infection during the course of treatment. The rate of healing and the general progress of the injury toward recovery, the amount and character of the drug used and the method of application are all carefully recorded. Frequent discussions are held between the many workers engaged in this study, methods are compared and results are evaluated and as new and promising procedures are developed, critical trials are arranged to test their efficacy. At this point I may say that through the medium of the National Research Council continuous liaison with the armed forces is maintained so that new and useful methods quickly become available for field application.

Because of the unique characteristics of the mechanical warfare of today, burns have assumed a position of far greater importance than in previous wars. Just as units for the study of surgical infections have been set up, so at a number of places special groups for the intensive study of the treatment of burns have been organized. Burns occurring in civilian life are congregated at designated hospitals. Specially trained men compare the most modern methods of treatment and assess their value. Through the medium of frequent meetings comparison of results takes place, and as new techniques become perfected thorough testing is provided.

As an illustration of the rapid progress in chemotherapy it is interesting to describe in some detail the most recent development. In 1929 Dr Alexander Fleming, an English bacteriologist, discovered that a certain mold, *Penicillium notatum*, when cultivated in a suitable growth medium manufactures a substance which checks the multiplication of gram positive bacteria—the usual causes of suppurative processes and of septicemia or blood poisoning. This discovery was at first largely of technical interest. Within the last three years, however, its use has been extended with success to the treatment of human infections. At first only small and inadequate amounts of the material could be prepared. Intensive study of the processes of cultivation of this mold by scientists in governmental, university and commercial laboratories is resulting in the production of increasing amounts, so that the scope of its use in human disease is being rapidly extended. This substance is many times more active than the sulfonamide drugs and is useful against the same types of bacteria. It has the additional advantage of being effective against certain organisms such as the staphylococcus, a frequent cause of septic infection, a field in which the sulfonamides have proved to date to be of very limited value. There are indications that it may be of value even in gas gangrene, one of the most dangerous and resistant to treatment of infections encountered in the first world war. While still in the experimental stage, it is hoped that with improvement in methods of production this new and most effective substance may before long become widely available.

Before soldiers wounded on the field of battle can receive effective treatment varying periods of time are likely to elapse owing to transportation difficulties. To meet this situation treatment units are established as near to the lines of battle as practicable. Nevertheless time is lost as the result of the numbers of casualties

and the difficulties associated with collecting the wounded. In certain instances the wounds themselves are initially of very severe character. During this total period and for these and other reasons a serious condition of shock may develop. This is one of the major medical problems of warfare. In order to study methods of preventing and combating this serious condition, numerous investigations requiring the time of a large number of specially trained medical men have been organized. Important facts are being brought to light and improved therapeutic procedures are being developed. One of the newer and most valuable of these is the use of blood and blood substitutes. In recent years blood banks have been successfully organized in many civilian hospitals so that whole blood will be immediately available in case of emergency. As a substitute for whole blood, blood plasma has been found to be extremely satisfactory. With the cooperation of the American Red Cross, blood collecting centers have been set up throughout the United States. The blood after collection is processed and the plasma separated off. The plasma is then dried in sterile containers and packaged in convenient form with the necessary amount of diluent. The plasma can be reconstituted and made ready for use with a minimum amount of effort and delay. Because of its dry condition it withstands extreme variations in physical environment without loss of therapeutic value. Abundant reports from the front already indicate the life saving value of this material in controlling the dangerous effects of shock and hemorrhage. An extensive search for other blood substitutes is being actively carried on and certain ones of promise are already receiving preliminary trials.

As a by-product of the search for blood substitutes for the first time, many purified components of human blood are being prepared. The potential usefulness of these materials is only beginning to be explored. That it may be great seems likely, since blood carries most of the essential substances necessary to life. I may mention that a purified globulin has already been obtained which is capable of protecting exposed individuals against certain types of infectious disease.

Although the ancient plagues of armies are today much less prevalent and better knowledge exists for their effective control, nonetheless in the prospective likelihood of increasing social disorganization and demoralization their potential dangers cannot be overlooked. A number of investigations are therefore being fostered with a view to improving the methods of control and treatment of the most important infectious diseases. Special attention is being given to influenza and pneumonia. The nature of the infecting agents and their method of spread are being studied and several experimental investigations are under way whose purpose is, if possible, to provide a practical method of preventive inoculation. Intensive studies of typhus fever are being carried out and progress is being made in methods for controlling the insect vectors of this disease and in the development of a protective vaccine. Modern and recently developed techniques are being utilized for the improvement of protective inoculation against dysentery, cholera and bubonic plague, and the usefulness of the sulfonamide drugs in the treatment of these diseases is being explored. The epidemiology and control of streptococcal infection, one of the most important causes of death during the last war, is being studied both in the laboratory and in the field by a large group of experienced investigators.

In the realm of infectious diseases a unique organization has, with great foresight, been set up under the leadership of Col. James S. Simmons of the Office of the Surgeon General of the Army and of Dr. Francis G. Blake of Yale University. The particular responsibility of this group is the survey and care of the health of soldiers in the many military installations in this country. A number of commissions of specialists have been organized and funds provide for the expenses of their work. These commissions carry on investigations in different medical laboratories throughout the country and a certain number are always prepared at short notice to go into the field. In fact a certain number are continuously working on special problems in camps in different parts of the United States. The range of activity is very broad and includes investigation of such diseases as influenza pneumonia, measles, scarlet fever, rheumatic fever and other streptococcal infections, meningitis, virus diseases of the central nervous system and tropical conditions. Special attention is being given to the development of methods for disinfecting the air of barracks and hospital wards in order to limit the spread of infectious processes within these areas. The health of the armed forces has been unusually good during the period of mobilization and training. This is particularly fortunate, since epidemics arising in military establishments not infrequently spread to the civilian population.

INTERRELATION OF WAR AND POSTWAR PROBLEMS

Although my presentation has been fairly long I have covered but briefly only a portion of the many medical activities that are in progress as part of the war effort. The emergency has greatly sharpened our vision and has liberated large stores of energy and enthusiasm. These forces fortunately have both the direction and the means necessary to realizing their objectives. Scientific bodies, universities and governmental agencies are utilizing the opportunities to the fullest possible extent. Both immediately practical and fundamentally significant knowledge is being gained. Though I have made no specific mention of postwar medical problems, it must be obvious to all that medical questions arising from war are closely interrelated with those of postwar periods and that knowledge gained and applied in wartime is equally useful in times of peace.

DISCUSSION

DR. FRANCIS G. BLAKE, New Haven, Conn. Trends in scientific research, like trends in most of the activities of men, are greatly influenced by the social, political and economic setting in which such activities are carried on. This could be no better illustrated than is illustrated by the impact of the social setting of war on scientific research. While it may be true that the impact of war on scientific research has only accelerated a trend that had already begun to appear, it certainly has had ever greater influence on that trend. That trend is a trend toward cooperative investigation in research. This has become all the more necessary because of the increasing complexity of techniques, the necessity for the application of the techniques of physics and mathematics and chemistry and many of the fundamental sciences to the problems of medical research. Not only has it accelerated the trend toward cooperative research by teams of investigators, but, under the necessity of making the results of scientific investigations of immediate importance to the war effort available as rapidly as possible, it has resulted in a much more free and extensive exchange of the results of current research among those investigators who are carrying on work in a particular field, such as aviation medicine or infectious diseases or blood substitutes.

Directed research by committee organization may have some drawbacks—no one, of course, would deny that. Under the impact of the war, however, this type of research cannot be deplored, certainly, because there are immediate practical problems for which the armed forces must have prompt solutions. In fact, their demands for prompt solutions are often so urgent that they wish a solution or an answer before the scientific research is able to give a scientific answer. This type of research in the present setting of society, a competitive, internationally competitive, society is by no means to be deplored. It has other beneficial effects, I am sure, in perhaps bringing some investigators out of their pleasant and quiet ivory towers and making them really think whether the problems they were working on before were of true significance or only providing them with an opportunity not to meet and answer the real questions of life. Yet there is a danger in too much organized committee research, not for the immediate social setting of wartime but for the postwar period. That danger, I think, is perhaps not a serious one, but it is certainly true, or at least I would feel that it is true, that too much group and organized research may tend to delay the development of individual initiative and curiosity in investigation—the desire of the individual to answer a question by investigation, which he is unhappy about until he has answered it.

What the present trends in research will be in the postwar period, no one, I believe, can predict. It will depend, as I tried to indicate at the outset, on what the philosophy of society is in the postwar period, whether it is to be a completely organized and directed society or whether it will again become a society in which at least a reasonable amount of individual initiative may be exercised to answer the questions which intrigue those who are engaged in scientific research.

DR. LEWIS H. WEED, Baltimore. Medicine has a unique opportunity here to go ahead in a surprisingly accelerated fashion to meet the practical problems which military medicine presents, for there are problems in military medicine which civil medicine does not meet. Certainly, if one contemplates merely the field of aviation physiology, one realizes that while, during the last war, there was tremendous activity in the research laboratories relating to the problems presented by the airplane, that research, as far as the human element is concerned, practically became nil during the intermediate period. It has required enormous stimulation in order to get the necessary research programs under way. Military medicine will carry on in the postwar period because of the tremendous necessities that postwar Europe and the postwar world are going to present in the problems of infectious diseases, the problems of nutrition, the problems of migration of peoples. We have an opportunity during this period to create a new type of military medicine. I am very happy that the Navy has gone ahead and built its own research laboratory which will be devoted to the problems of navy medicine, not only during the period of the war, but as a continuing activity, bringing in civilian scientists and naval officers into this general program. A similar project is, I believe, under way in the Army. I hope that we shall in the next war have a body of fact which has come out of the researches, both in the Army and in the Navy Medical Corps, which will enable them to carry on in these problems of military medicine.

DR. A. N. RICHARDS, Philadelphia. I am grateful for the privilege of being given this opportunity because there is one thing, it has occurred to me, needed saying. Allusion has been made to it, but it could be amplified a little bit. A trend has been occurring to my knowledge and in my experience for twelve years at least, perhaps fourteen, which has resulted in a closer cooperation between university research institutions and commercial research institutions. The present emergency has intensified that cooperative effort, and it seems to me that it is of the greatest importance. Among the commercial organizations, particularly those that are represented in the list that you see on your program, there are abilities and funds which you see on your program, medicine of ten years ago or twenty years ago was not realizing, which they did not altogether trust. I think that trust is being established on the basis of a tremendously admirable spirit in those industries.

HEALTH—A WORLD PROBLEM

F P KEPPEL, LL D
NEW YORK

Program committees are arbitrary people and I find myself put down for a topic I am not equipped to discuss. Please remember while I tell you what I can, that the choice both of topic and of speaker was not mine. For many years I have stood on the side lines of medicine and public health first as a university officer at Columbia, then in '17-'19 in our War Department where I saw much of General Gorgas and the doctors he gathered round him from Popsy Welch down, then for two years with the Red Cross where I had the privilege of seeing something of its great work in Europe in '20 and '21. And then I was for nineteen years an executive of the Carnegie Corporation. In medicine and public health we were quite content to play second fiddle to the Rockefeller Foundation, but we did some things of our own. I hadn't realized how much until I saw an analysis of the Carnegie Corporation grants made by my successor and found that since its establishment \$12,000,000 has been spent for these purposes.

What I remember best was not the big grants but some of the smaller ones—the eight thousand dollars which had much to do with the discovery of insulin. Since then insulin has cost us twenty or thirty times as much for its purification. We gave Hopkins some money for general endocrine studies to be directed by Dr. Abel, who had retired from his professorship and was no longer a youngster. In the middle of the studies Dr. Abel's leg was broken in a street accident and he thereupon gave a demonstration of that devotion to responsibility which is one of the glories of your profession. When the leg was set and mummified in a cast did he go home? No, he had himself moved into his laboratory, and the research went on without a hitch. Later on Lewis Weed, with very moderate financial help from the corporation, has done a great job to stimulate the spirit of research in dental education.

One particular part of our work touches world health conditions more directly. Mr. Carnegie set up a special endowment for the British dominions and colonies, and that brought us into contact not only with Canada but with Australia and New Zealand, with the Union of South Africa and with the colonies in tropical Africa and elsewhere. A good part of our money went into fellowships and travel grants. The men and women selected not by us but by local boards could go where they pleased, but we had a wonderful demonstration of the degree to which those lands turn to us for help in medical and health leadership—it's not for the record, but definitely more than they do to England. Believe it or not, they have a higher opinion of American education than we seem to have ourselves, and most of these grants were given to teachers to come to the United States, but grants for medicine and public health were a good second.

And now I'm on the side lines in Washington. One of my two jobs there is as a member of the War Relief Control Board with Ambassador Davies and Charles P. Tait. Among other things we are doing what we can to help the American people to realize that government

aid through Lend Lease and otherwise is not enough, no matter how generous it may be. The good will offerings of individual Americans carry a message of love and understanding which must be measured not in terms of dollars and cents but in terms of spiritual therapy for the giver and for the recipient. And of course anything that reaches the individual in the suffering land—clothing, food, drugs and medical supplies—has its practical therapeutic value as well. The opportunities are now limited, but, as new territory is opened up by military victory, the opportunities will increase and so I am sure will the gifts from our people.

I have another job in Washington, as a member of a two man board of appeals set up by the President to pass on applications for immigration visas and in these days that is chiefly a question of the admission of refugees. Let me say at the outset that this is a question about which the American people are both ignorant and misinformed. There seems to be a widespread impression that great hordes of unwashed and ignorant foreigners are beating at our doors. The facts are that if every single application received in the year 1942 had been approved and if every single holder of a visa had been able to get here, the total would have been less than 10 per cent of the immigrations under the quota system in a normal prewar year. But less than half the applications are actually approved and a high proportion—I should say fully one half—of those who were granted visas have not been able to use them. You all know what happened when our consulates in southern France were closed last fall.

Let me tell you also that the proportion of these applicants who have had university training and professional or scholarly or creative experience is very high. I haven't the exact figures, but I believe they compare favorably with the proportion in the United States today. The anthropologists have stolen the word culture from the rest of us, but I am using it in the old fashioned way when I say these are largely people of culture. If you see pretentious and vulgar men and women who have bribed their way across Europe and across the Atlantic, and we all do see such people, remember that they are very much the exception and not the rule.

Now as to the relation of all this to world health. It has been my duty to go over more than twelve thousand of the dossiers of these applicants and it surely is an extraordinary series of human documents. They show all too clearly the physical effects of persecution and hardship. In case after case where a husband and wife had applied together the application had to be changed because one or the other had died in a concentration camp before the case could come up for consideration.

And let me tell you something else. We made a statistical study of the applications from Europe and we found that more than 40 per cent of these people had already moved from one sovereignty to another before the days of armed invasion or organized persecution. In many instances they had moved three and even four times before their applications were filed. The modern wandering of the tribes had started years ago.

For such people the question of physical health is bound to be tied up closely with that of mental health. I am sure you all feel this but perhaps I can confirm your feelings. Over and above the strain which each one of us is under in wartime these people have sui-

fered humiliation and insult and physical brutality. Their families have been torn asunder; they live not only in hardship but in uncertainty from day to day. Until they reach a haven of refuge they can make no plans for the future.

And now a final word on a somewhat embarrassing topic. As I said, a large proportion of the applicants are professional people. Among them are many members of the health professions—doctors, dentists, nurses, research workers. How can we use these people to the best advantage of the United States? In all these callings we have today both a numerical shortage and a serious maldistribution. In all these callings American men and women have left their jobs and the path of professional advancement in their communities to serve their country and have done it without an instant's hesitation. We all share in the responsibility to protect those jobs for them to return to. Can we have it both ways? Can we use these immigrants, many of them highly trained and still protect our own fellow citizens? It's not an easy question. May I in closing offer a suggestion which is wholly personal and unofficial? I'll put it in the form of still another question.

Might it be possible for the Manpower Commission as a temporary war measure to ask for the granting of special licenses to immigrant aliens the right to practice being restricted in each case to some community designated by the commission—some mushroom industrial center in the South, let us say—and the license to be good for the duration of the present emergency only? Think it over—and thank you all for having listened so patiently to my wandering remarks.

522 Fifth Avenue

WORK OF THE RED CROSS IN POST-WAR MEDICAL REHABILITATION

RICHARD F. ALLEN

Vice Chairman, American Red Cross

WASHINGTON, D. C.

For a person who has spent some three and a half years out of the last four years abroad usually in the midst of problems created by this war, attempting to bring some relief to the millions in distress, it is a great comfort to me to be here and to see this group of men and women who are giving serious consideration to postwar problems.

In every place I have been, I have seen groups of people meeting to discuss this problem. In most of the places I have been, they could not discuss the problem at banquets because of food regulations and sometimes because it was not safe for large groups of people to be together in one room. In London I had the great pleasure of participating in the discussion some eighteen months ago at the Royal Institute of Science, in a meeting where they discussed postwar problems. At that meeting were representatives of practically all the governments that are now making their headquarters in London because their countries are occupied by the enemy. Also represented at that meeting were the best brains and talent in Great Britain.

In France the discussions were rather on the quiet side. There wasn't much discussion of postwar problems before the fall of Paris, and after the fall of Paris of course, no groups of people could get together and

discuss freely the problems. But in the relations which I had over a period of many months with the leading health authorities and scientists in France I never met with them privately or in small groups that they did not discuss what we were going to do in postwar relief.

I was in Iceland and I was rather surprised—I don't know why I should have been—to hear the doctors and the scientists there discussing the same thing. And now I have just returned from North Africa, and one of the questions that always arose was what America was going to do about postwar relief. It is pitiful how they depend on us to do something about it. It will be a tragedy if we let them down. That is the reason why it is a great comfort to me to see this group of men here tonight considering some of these postwar problems.

I wish I could tell you what the American Red Cross is going to do in medical rehabilitation following this war. I don't know and I don't believe anybody else knows at the present moment. I do know that we shall do something. Just what that something will be it is hard to say. But when postwar relief gets under way there is no question in my mind that the American Red Cross will be taking a very prominent part in the giving of medical relief and in medical rehabilitation throughout the world.

The reason why I am so sure this is going to happen is that we have had more experience in giving relief throughout the world today than any other organization in the world. I will go back a little bit. I hope I won't bore you with getting into history. I will make it brief. I will go back and sketch rather hastily what was done immediately after the last war.

The American Red Cross rendered very unusual services to the Sanitary Corps of the United States Army during the last war. We had great quantities of medical and hospital supplies in warehouses both in France and in America. The Army at the end of the war also had huge reserves. In the spring of 1919 the Army gave \$25,000,000 worth of those medical supplies to the American Red Cross to be distributed throughout the countries of Europe which were being rehabilitated. Unfortunately, neither the American Red Cross nor any other agency had worked out a long-time plan. I think the emergency job we did was an excellent one. I think that a good many things which we started with the idea that they would be permanent fell short of the mark, although there are indications as you travel through Europe that many of the dispensaries, nurses' schools and hospitals which we established are still operating and are taking the leadership in those countries.

We distributed huge quantities of medical and hospital supplies in Poland, the Baltic states, Czechoslovakia, Austria and Hungary, Rumania, Bulgaria, Montenegro, Greece, Albania, northern France and Belgium. I hope I haven't forgotten some of the countries in which we operated. We restored hospitals. A good many of the hospitals had been damaged by enemy action. All the hospitals were depleted of the stocks which they needed to care for the civilian population. We worked with new and inexperienced health departments in new countries. We weren't particularly well equipped to do that job. I think we probably made quite a few mistakes in it, but the sum total is an excellent one.

Between the two wars what happened? We had formed many friendships and acquaintances throughout

Europe in those days. Then we left Europe. We were an emergency organization. We came home. The reason why I mention that fact—of which we are not particularly proud—is to impress on you how important it is that any agency which does health work in Europe following this war does not go to stay only a short time or if some agency does go to stay only a short time, it should be a part of a big plan which would provide for a proper follow-up. I need not stand before this group and tell you that you can't do really constructive medical rehabilitation in a short time. It is a long-time problem requiring great patience and it requires a lot more patience outside the United States than it does inside the United States.

The Rockefeller Foundation and some British organizations, perhaps some other American organizations, carried through, and through their work the health departments throughout Europe are in a considerably different position than they were following the last war. Most of the countries in Europe today—and I am talking about Europe mostly, although the point is good for the rest of the world too—have fairly good health departments. They have fairly good staffs of doctors and they have some staffs of nurses, and any agency or agencies that go into Europe doing medical rehabilitation will make a great mistake if they do not lead the local people to take the leadership in giving that relief. It would be a great mistake if the United Nations or the United States or Great Britain or any other country should go in and impose a plan on these countries. They must work out their own problems with our help.

Since the current war has been under way, what has been going on? The American Red Cross has sent huge quantities of medicines and hospital supplies to Great Britain. We have sent huge quantities of supplies to Russia, China, India, the Middle East, to France before the fall, and then lesser quantities to Belgium, Norway, Yugoslavia and Greece. How have those supplies been distributed in those countries? In all cases they have been distributed in close cooperation with the established health authorities in the country and with the cooperation of both the public and private authorities on health.

I will tell you one experience which I think will illustrate my point. When the Germans came into northern France they took over practically all the hospitals in the nine departments north of Paris. The civilian population came back from the south where they had fled and there were no hospitals in northern France. Neither were there any available supplies because the Germans had taken the supplies too. Fortunately, just before the fall of France a ship had left America loaded with two million dollars' worth of medical and hospital supplies. These supplies had been gotten together with the idea that they would be used behind the lines of the French and British armies both for the armies and for the civilian population. But before the time the supplies could be gotten to France the story was all over and the Germans were in command. There was no French army in the field.

After great difficulty, we shipped most of those supplies up to the north. There was no great need for medical and hospital supplies in the south of France. We had a terrible time working out a plan with the Germans for the distribution of those supplies. Every-

thing we did had to be approved by them. The head of the health department of France, the Rockefeller Foundation representatives who were there, the French Red Cross and several French agencies conferred with us on how those supplies could best be used, and we finally decided that they should be distributed in these nine departments north of Paris.

We made a hasty survey and found that the hospitals were in old museums, in hospitals de charité and in buildings which were certainly never designed to be hospitals. They had no sanitation, they had no heat and they had no equipment except for the very ordinary, common things that they could buy on the local market.

We finally got the Germans to agree that they would not disturb any of these supplies. We were rather shy in trusting them. I think you will understand that. They finally did agree, however, and Berlin itself sent out word to the commanding officers in each section that the supplies were not to be touched by the Germans.

We shipped into that district north of Paris great quantities of gauze, ether and cotton, surgical instruments, drugs and medicines, and all those things were used in the simple little emergency hospitals that were set up in order that the French population might be cared for. We did that with the full support of all the French doctors and nurses and social workers in the north of France. It was a great success. It was quickly done, and it saved untold distress.

In this matter of postwar relief it seems to me that the most important thing is an understanding of the people whom you are going to serve—making the point, again, that we help them to help themselves. Language is a great difficulty, of course, and there are not a great many doctors and nurses in the United States who have language accomplishment. Language accomplishment is not the most important qualification, however. The most important qualification is the ability to convince the people for whom we are caring that we are trying to help them to help themselves.

Over in North Africa recently, when the President arrived, everybody was excited. One afternoon, when it was known that the President was there, or about twenty-four hours after he arrived, one prominent Frenchman said to me "Mr. Allen, is it true that your President speaks perfect Arabic?"

I said "I don't know. Our President is a very remarkable man, but I doubt very much if he speaks perfect Arabic."

This Frenchman said "Well, all the reports that come to me say that he is carrying on conversations in Arabic with the Arabs."

"Well," I said, "if you knew our President as well as we do you would know that he could know about three words of Arabic, smile and wave his hands, and they would be convinced that he was wanting to help them."

That is what I mean about doing this postwar job. Let us not just be coldly efficient. Let's do the thing and have a heart in it too, because if we don't we are going to fail in one of the biggest opportunities any people in any land ever had. I believe thoroughly that the American Red Cross is qualified to play an important part in the medical rehabilitation of the world. We have had the experience, we have the acquaintanceship and we have a prestige which is beyond question.

INTER-AMERICAN COOPERATION

NATHAN A. ROCKEFELLER

Coordinator of Inter American Affairs

WASHINGTON, D. C.

It is a privilege to have the opportunity to meet with you the nation's leaders in public health and medicine at this National Conference on Planning for War and Postwar Medical Services. The memory of Dr. Carlos Finlay and his great contribution to mankind is an ever present inspiration in carrying forward those services which have made possible the tremendous advance of civilization during the past century.

Medicine whether in war or in peace knows no boundaries. It is universal in its concept humanitarian in its philosophy giving aid and assistance to the weak and oppressed in all lands. While a war torn world is bent on destroying lives it seeks to preserve and build.

The Axis has plunged the world into total war—a new form of warfare in which the military, the most spectacular phase of total war, deals only the last of a series of destructive blows. The Axis prepared for this final phase by cunningly conceived plans for the domination and corruption of political life the destruction and control of economic life and the demoralization of the will and morale of the people. The Axis plan envisioned total destruction and the enslavement of the world but it underestimated the vitality and determination of the freedom loving peoples of the world. In this hemisphere in Europe and in the Far East these peoples have rallied from the blows of the last few years and are now gaining the offensive on all fronts.

In this total war the republics of the Western hemisphere have drawn closer together and greatly strengthened their machinery of cooperation. Jointly the American republics worked out a plan of action at the Rio de Janeiro conference in January 1942 on the basis of which we have mobilized manpower and material resources to meet the Axis on all fronts of this total war. Swift, positive action was initiated to stamp out Axis subversive and propaganda activities, to prevent Axis sabotage and economic domination within the hemisphere. Defensive and offensive military strategy of the hemisphere, including the development of a network of air and naval bases, has been developed under the guidance of the Inter-American Defense Board, which is made up of the leading military strategists of the twenty-one American republics.

But the power of a nation is no greater than the strength of its people, whether on the fighting front, on the farm, in the factory or in the home. The ministers of foreign affairs at Rio foresaw this and realized that the success of this total effort would depend on the physical strength and moral fortitude of their people on the hemisphere home front. Therefore a resolution was passed recommending that the American republics take appropriate steps "to deal with problems of public health and sanitation, by providing, in accordance with ability, raw materials, services and funds."

This joint determination exemplifies the inter-American way of life—the way of friendship and cooperation. It is in stark contrast to the Axis way of life—the way of domination and death.

Thus the program of health and security formulated at Rio was designed to meet Axis total aggression on three main fronts—the military front, the production front and the home front.

First, on the military front the ministers recognized the possibility of the danger throughout the hemisphere of a situation which was so tragically described by last reports from Bataan. They indicated that the troops were unable to carry on because 90 per cent were ill with malaria and dysentery and that all forces were weak from lack of food. Control of malaria and the development of adequate food supplies in strategic areas throughout the hemisphere were critical factors in military strategy.

Secondly the same program was essential for the development and production of critical materials, such as rubber hemp manganese tin and hundreds of other raw materials essential to the operation of war plants of the United States. Sickness and hunger lay in the unexplored jungles where the great riches of rubber and other tropical production went virtually untapped. Strong and healthy men with their families, dared not face the ravages of disease and lack of food. Therefore the flow of raw materials was dependent on the work of public health doctors sanitary engineers and agriculturists in such areas as the Amazon Valley extending for over 3,000 miles through the heart of the southern continent.

Thirdly, the morale of the people and the political stability of the other American republics was threatened by increasing wartime economic dislocations. Normally our neighboring republics depended largely on exports of coffee, cocoa, sugar, bananas, grains. Coffee was accumulating in the warehouses of Brazil, bananas were rotting on Central American plantations. Cuba was having to reduce her sugar grind, all because shipping was increasingly being used to do the primary job of moving men and supplies to the fighting fronts overseas. Rail and motor transportation suffered from lack of fuel, repair parts and tires.

Unemployment was rising as factories closed for lack of materials or because of the curtailment of activities on banana and coffee plantations. The problem was aggravated by the increasing scarcity of goods and rising prices. These conditions in turn threatened social consequences. They were leading to malnutrition, ill health social unrest and weakening morale. The governments of the other Americas derive substantial parts of their revenues from export and import duties. Thus the shrinkage of foreign trade reduced the capacities of these governments to provide necessary help to their people when it was needed most.

Here, in short, was a stern test of the good neighbor policy. The ministers at Rio realized that the type of bold decisive action necessary to meet these problems would be possible only through joint action. They realized that the hardships and sufferings on the home front could play into the hands of the Axis agents,

skilled in the art of spreading fear, mistrust and confusion in the hearts and minds of people.

Therefore immediately after the conference in accordance with the resolutions passed, the Office of the Coordinator of Inter-American Affairs acting on behalf of this government, launched a program in cooperation with the governments of the other republics. This program is summed up in the term basic economy and the work is being carried out in the fields of health, sanitation, food supply and nutrition. Let me tell you in some detail of this work, because it may be of interest in connection with the problems you are discussing tonight. It illustrates graphically how the Americas are jointly facing and meeting the grave problems of the war.

To carry out this program in accordance with the Rio recommendations, *notes of agreement* have been exchanged between the United States and fifteen of the other American republics, calling for joint undertakings in the field of health, sanitation, nutrition and food supply. In each case, after the exchange of notes cooperative programs were mapped out by representatives of the Institute of Inter-American Affairs, an agency of the Office of the Coordinator, and officials of the respective countries. The actual execution of the work is carried out by a "servicio cooperativo" which is established in each country under the minister of public health or agriculture depending on the nature of the program.

At the present time over a thousand projects and activities are being carried on in these fifteen countries. Of these, about two hundred involve buildings constructed of local materials, including hospitals, health centers and nursing schools. Another two hundred are sanitary engineering projects, such as drainage for malaria control, improvement of sewerage and water supply. Many hundreds more are for the expansion of agricultural production in deficient areas—they include irrigation and storage facilities as well as general crop and livestock development.

Mobility of medical service is a prime requirement over the vast areas where strategic materials and defense bases are being developed. Consequently the inter-American health and sanitation program is producing unique facilities. For example on the Amazon and its tributaries a fleet of more than thirty boats has been assembled and transformed into floating dispensaries. The majority of these are small launches which carry four beds and are staffed by one doctor and two nurses. They service the rubber worker on the remote tributaries of the Amazon. Likewise along the inter-American highway in Central America motor trucks have been equipped as mobile dispensaries.

As you know there is a shortage of material and trained personnel but fortunately most of the technicians and other trained personnel for these programs are being provided by the other Americas. The ratio of doctors and engineers is about one from the United States to every twenty-five from the other Americas. The other Americas likewise are contributing substantially in the way of funds, materials and equipment.

The projects provide sanitation for areas around defense bases, they provide health services for millions

of workers on the production fronts of the Amazon and Central America in the mining regions of the Andes and Brazil on fiber growing projects in Haiti.

While malaria control is of primary importance, the work also aims to reduce the human toll taken by such diseases as tuberculosis, plague, typhus, dysentery and *chagas*.

The campaign against disease must be a rounded program. Disease germs are not isolationists. They move about more freely now with the development of highways and airports. For example, the death dealing *gambia* mosquito which ravaged northern Brazil was brought to this hemisphere by airplane from Africa. Inter-American transport by highway and air will be greatly accelerated after the war and will increase the need for our cooperation in the war on disease.

The battle against malaria is being fought under the most difficult conditions. In some places work is being done along thousands of miles of riverfronts. In others, supplies have to be carried over the Andes by airplane, motor truck, canoe, pack mule and even on the backs of men to medical outposts. To get construction materials it has been necessary in some places to erect brick kilns and saw mills. In Guayaquil the ingenuity of doctors and engineers produced one hundred beds for the hospital out of twisted wire and old pipes.

Doctors and sanitation engineers of the Americas toil through jungles, navigate swift mountain streams on balsa rafts and live for weeks and months in forests far from the comforts of home. The war they are waging against disease is essential to victory and a vital part of the total war effort.

Disease and hunger are twins born of the same conditions. They are twin problems in the vast Amazon country as in other places where development of strategic materials is under way. Brazil is moving fifty thousand additional workers for rubber production into the Amazon. The new workers must be fed as well as protected against disease.

Ordinarily with adequate shipping food had been brought in from surplus areas. Now with the shipping shortage it is essential to grow more food locally. Brazil and the United States undertook a joint program and are contributing equally to a \$4,000,000 project for expansion of food production through the whole of northern Brazil. Food growing projects likewise have been arranged in Costa Rica, Panama, El Salvador, Honduras and Paraguay. Others are in prospect. These are designed to encourage the growing of vegetables, fruits and dairy products for local consumption and to supply the military in defense areas. The Panama Canal forces are receiving increasing quantities of food from nearby countries thus saving valuable shipping space.

In Honduras, employment has been provided for two thousand former banana workers on a transcontinental road to help tide a banana growing area over the sudden loss of its economic mainstay when banana exports to the United States were curtailed drastically because of the lack of ships.

This basic economy program is a broad concept of good neighbor action on behalf of the peoples of the

Americas. Therefore let us look at it from the point of view of the individual. Take the case of Jose, a Brazilian farmer in the northern state of Ceara. Jose has been through lean years of drought. He can't make ends meet. His family is hungry. He would like to get a new start in the newly developing rubber area in the Amazon. But the rubber trees are 2,000 miles or more away and he has no money for travel. He wonders too how he would eat and keep well. So Jose thinks perhaps he had better stick to his dry acres.

But Jose changes his mind. Why? Because Brazil and the United States have gotten together to solve just such human problems. Doctors and engineers have gone to work. They are distributing antimalarial drugs. Jose finds that food and medical care will be provided. And so after a long trek to the Amazon Jose starts life afresh as a rubber tapper.

Or take the case of Pedro, a banana worker in Nicaragua. Pedro had been making good wages but he did not have much in reserve when he lost his job.

Then one day Pedro heard a fiber development project was starting nearby, that his government had entered into an arrangement with the Yankees to undertake this program. Pedro didn't ponder the abstractions of inter-American cooperation. But he did know that the project meant work, wages, food for his family. And Pedro has become one of the millions of human beings who are seeing in tangible deeds what being a good neighbor means.

The stories of Jose and Pedro can be multiplied against a variety of local conditions and production problems—guayule workers in Haiti, workers on a rail construction project in Brazil's iron-rich Rio Doce Valley, rubber gatherers in Central America, miners in Bolivia, quinine plantation workers in Central America.

Jose and Pedro are the human foundations of the Americas. They can understand the meaning of inter-American cooperation when it takes the tangible form of medicine, hospitals, screened shelters, food. Jose and Pedro can understand the economic value of a new sisal plantation or a new road. They mean a chance to work and the hope for a better future for their children. Thus Jose and Pedro are coming to see that through inter-American cooperation the fight for freedom and for opportunity is their own fight.

This basic economy program is to strengthen the human resources of the hemisphere, both for the war period and for the long pull after the war. It supports urgent immediate needs for wartime defenses and production. It bolsters morale against the shocks and hardships of wartime dislocations. It builds for the future of inter-American unity on a foundation of inter-American friendship and cooperation. The hospitals, nursing schools, health centers, the new practices of agriculture, the new roads and, most important, the economically productive and bodily sound Americans will provide the basis for expansion of trade among the Americas and a steadily rising standard of living. The resulting economic prosperity throughout the hemisphere will afford the best assurance for the social security and the peace for which we are fighting today.

Commerce Building

AMERICAN MEDICINE'S CONTRIBUTION TO POSTWAR MEDICAL SERVICE

MORRIS FISHBEIN, M.D.

Editor, Journal American Medical Association and
Hyer, the Health Magazine

CHICAGO

Starvation and epidemics do not recognize national or racial boundaries. Typhus in Russia, plague in China, dysentery in Africa or famine in Greece may mean disaster to Italy, Germany, Japan or the United States. Before this war is over the people of the totalitarian governments will awaken to the fundamental biologic truth that in a world like ours every man is his brother's keeper.

The statesmen who are concerned primarily with the economic rehabilitation of the war-torn world have recognized the vital character of medicine's contribution. In an address made by Sumner Welles, Undersecretary of State, at Rio de Janeiro on January 15, he said:

My government believes that we must begin now to execute plans, vital to the human defense of the hemisphere, for the improvement of health and sanitary conditions, the provision and maintenance of adequate supplies of food, milk and water, and the effective control of insect-borne and other communicable diseases. The United States is prepared to participate in and to encourage complementary agreements among the American republics for dealing with these problems of health and sanitation by provision, according to the abilities of the countries involved, of funds, raw materials and services.

We are concerned, however, not only with the problems of the Americas. That would be isolationism as much as an attempt to limit our concern for the postwar world wholly to the United States. The scope of the world's needs was well expressed by the Hon. John G. Winant, our ambassador to the Court of St. James, at Durham on June 6, 1942. He said:

When war is done, the drive for tanks must become a drive for houses. The drive for food to prevent the enemy from starving us must become a drive for food to satisfy the needs of all people in all countries. The drive for physical fitness in the forces must become a drive for bringing death and sickness rates in the whole population down to the lowest possible level. The drive for manpower in war must become a drive for employment to make freedom from want a living reality.

The ideals of this platform merit the support of every one who loves his fellowman. Particularly will they have unanimous endorsement from the physicians of our nation, who know more intimately than can any others the relationship of poor housing and malnutrition to sickness and death and who know as well the importance of scientific diagnosis and treatment in overcoming the devastation that disease can effect.

The nature of the problems is clear. The answers, however, are not quite as obvious. Many a statesman is devoting serious consideration to the economic aspects of world reconstruction and rehabilitation. The costs of such procedures will no doubt fall most heavily on those portions of the world best able to bear them. Certainly some lands and some nations have been so completely devastated by the attacks of the aggressors and by the fact that they have been the battlefields on which the decision has been made that they can only beseech aid, offering little of their own as a help in the process. Until the sick and the starved and

Read before the National Conference on Planning for War and Post-war Medical Services, New York, March 15, 1943.

the disabled in Greece, Poland, Czechoslovakia, the Netherlands, Denmark, Norway, Belgium and France in China and in the South Seas have been restored at least to some degree of physical fitness, little can be anticipated in the contribution either of materials or of work by these shattered peoples. The obligation must rest largely on the more capable and the more wealthy of the United Nations to aid not only the peoples of the countries that have been most war torn but also the people of the nations that have been defeated. I would not presume to speak as one versed in the problems of world economics. I do know that the leaders who assume the responsibilities for speaking in these matters have already called and will expect to call more definitely in the future on the medical profession and the medical resources of our country to meet the needs of the world for medical care and medical services.

Following World War I many serious problems confronted medicine in all the warring nations. That experience indicates the importance of a careful consideration now of the demands that will be made and of the resources in men and materials that will be available for meeting those demands. The economic utilization of men and materials and the extent to which the morale of the men concerned is based on a wish for doing the most that can be done rather than on compulsion is likely to play a considerable part in the ultimate efficiency of the procedures.

THE SUPPLY OF PHYSICIANS

The medical schools of the United States have been for some years making available to the American people physicians adequate in number to our needs—in fact, more adequate in proportion to the total population than are available in any other country in the world. At the beginning of this global war we had one physician to every 700 people. By Jan. 1, 1943 we had established as a standard one physician for every 1,500 people, a number considered adequate to serve the needs of our population by the authorities assigned the responsibility in this matter. Great Britain today has one physician to approximately 3,000 people in its civilian population, and Sweden one to every 2,500. No one knows the ratio of doctors to population in Germany, but it has been said that in many parts of Germany it is one to 8,000 or one to 12,000. The number of scientific physicians available for the care of the population of China is so small as to be insignificant in relationship to its needs.

Admiral McIntire recently predicted that it may be necessary following this war to hold within the ranks of our Army and Navy at least one third of all the physicians who have been enrolled so that they may be available to aid medical service that will be required in the various parts of the world to which they have been sent. American medicine has already been planning to meet these needs. The accelerated programs in the medical schools, the deferment of the premedical and medical students, the Army training programs for premedical and medical students, the maintenance of internships and of residencies in the specialties are all part of the careful planning and of the program that was ultimately adopted.

Such information as is now available indicates that the medical schools of Belgium, the Netherlands, Poland, Czechoslovakia and France have been devastated and probably wholly discontinued. The great medical schools of Germany which were once her pride

and which were once accepted by all the world for their leadership, have become today the degraded tools of Germany's war-mad leaders. Today their restricted curriculum includes the unscientific philosophy of German racism and the concept that every man must be trained as a laborer and a soldier in his professional equipment. The restoration and rehabilitation of the medical schools of the world may place a tremendous demand on the physicians and particularly on the medical educators of our country.

A medical school consists not only of great buildings with laboratories and libraries but primarily of medical teachers. The world will need medical teachers as it has never needed them before. The medical schools of the United States and those of the Allied Nations capable of meeting the demands will need to welcome into their halls the young men of many of the nations of the Americas and of other portions of the world. Our own educators may be called to other parts of the world to aid in the reconstruction and revitalizing of their medical institutions. On the doctors of those countries who remain after the war will fall the major portion of the tremendous burden of the care of their own sick, but even for this service many of our doctors may be required.

Typhus or malaria anywhere in the world menaces our people unless we set up in those nations as well as on our own shores the effective barriers that preventive medicine has for epidemic disease. Without such barriers and without the scientists capable of establishing and maintaining them, the success of winning the war may be negated by the devastation and destruction of an epidemic like that of influenza which swept the world following World War I.

MATERIALS AND SUPPLIES

Modern medicine depends on the use of medicaments and equipment which have been developed as a part of the great advancement in medical science that has occurred during the past fifty years. During World War I we learned much of what a shortage in an essential drug can do. Some of us still remember the voyage of the submarine *Deutschland* and its cargo of salvarsan. We still remember the failure to duplicate the drug using the patents and the processes that had been supplied to our Patent Office and the manner in which our own great research institutions overcame those deficiencies. Today that story has been somewhat duplicated by the record of atabrine.

But many another mistake of World War I may yet be repeated in this global war unless we consider now the problems that are certain to arise. Colonel Shook has indicated today the nature of those problems.

Following World War I vast amounts of medical supplies sent by this nation abroad were sold at public auction, some of them given as an outright gift to the countries in which they were at the time of the Armistice. Some of the drugs, including narcotics which had been given to one nation were shipped back to the United States and sold in this country at prices below those of the same products made by American manufacturers in the postwar period. Some of the narcotics appeared in the illegal drug traffic of the world. Little consideration was given to the determination of the purity or quality of some of these materials which obviously were greatly deteriorated in shipment. I have heard that some of these drugs were still being reprocessed and sold in 1938. I know of tetanus that was caused by the sale of contaminated ligatures thrown on

the market after the war ended. I know that one manufacturer purchased back from the Army a considerable quantity of an antiseptic drug so that he might be able to sell it to the Navy, which still needed some of that product. I know that even in this war some 2½ tons of drugs have been shipped to one of the war areas without adequate consideration of the needs of the area concerned, the amounts of the specific drugs that might be required and, indeed, of whether or not some of them would be required at all. Certainly the time is not too soon to begin serious planning with relationship to the needs of the world for medical supplies.

Fortunately again for our country, the growth of our pharmaceutical industries during the past twenty years has been one of the most phenomenal developments of all time. These industries have supplied amounts of blood plasma through a cooperative effort with the Red Cross, the Army, the Navy and the people of this country so great that they beggar the imagination. During 1943 more than 2,000,000 people of this nation will contribute their blood for this purpose. They have supplied quinine and atabrine and other antimalarials in amounts sufficient to guarantee to the peoples of the United Nations and to the armies and navies and to the peoples of the countries in which the battles are being fought some control over this most devastating disease. They have produced the essential vitamins of which thus far we have knowledge in amounts sufficient to overcome at least the fundamental deficiencies that would have resulted otherwise in worldwide outbreaks of scurvy and rickets and many other diseases. They have met the demands for the sulfonamides, the miracle drugs of modern medicine in terms of tons and tons and tons. As a result pneumonia, which might have incapacitated many hundreds of thousands of men, has a death rate of less than 1 per cent in our troops. Whereas 1 in 3 of those who had meningitis in World War I died of that disease, the figures for this war are 1 in 20. From wounds of all types in the Solomon Islands and in Guadalcanal there was a death rate of less than one half of 1 per cent, which might have been 5 to 7 per cent had we been compelled to depend on the drugs and the methods that prevailed in 1918.

This is in large part the contribution of the American pharmaceutical industry. Practically every one of the great organizations in the field has received from the Army and Navy the award of the E which indicates the magnificent part it has played in the war effort.

Physicians, therefore, and the medical industries of the United States have done and are doing their part in the winning of the war. The health of our people is magnificent, as shown by the low sickness and death rates that have prevailed among us for many years. These accomplishments are a tribute to the quality of American medicine, to the United States Public Health Service, to our state and local health agencies and, perhaps above all, to the gradual evolution in the United States of our own system of medical service.

The movements of great masses of people to meet the industrial needs of the war created in many portions of our country problems of housing and feeding and disease which have been answered satisfactorily in most places by the cooperative efforts of government and private agencies. In many instances leadership has come from the industries concerned. In some areas organizations of physicians have done much to facilitate the provision of the factors necessary for health.

In some areas organized labor assumed responsibility. Such agencies as the Federal Housing Administration, the Farm Security Administration, the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, the United States Public Health Service and the Children's Bureau have cooperated with practitioners of medicine and with local and state public health officials to meet the needs of the emergency. Wherever such cooperation has obtained, the results have been most fortunate for the people concerned. The initiative has for the most part rested with the people themselves. The element of compulsion except through such pressures as arise from public and professional opinion has not been necessary to secure effective action.

COOPERATIVE ACTION

The time is not too soon for us to establish the necessary organizations for control of medical rehabilitation and reconstruction. Already in England there has been accumulated a mass of data showing the food situation in the occupied countries. There has been agreement on a basic list of drugs which will be needed in those countries as they are liberated. Estimates have been made as to the fundamental materials required for feeding 100,000 people of various nationalities. Plans have been drawn up for dealing with expectant and nursing mothers and for coping with the large numbers of cases of tuberculosis and typhus that are anticipated. Indeed the one death rate that has risen definitely in all the warring countries has been the rate for tuberculosis among certain age groups. Some committees are considering the steps that will have to be taken by instruction and propaganda to restore suitable standards of nutrition and to prevent the increase of infectious diseases. We know that it is possible for human beings to survive for a considerable period of time on something less than an optimal diet, but we know also that, the longer such minimal diets are used, the more extensive become the deficiencies and the more difficult their control.

An editorial recently published in the *British Medical Journal* indicates how our British colleagues have been considering the problem of relief following the war. The editorial said:

When the time comes for relief in Europe the Allied Nations will be united in a herculean task. The work must be carefully prepared beforehand, and plans are already engaging the attention of many persons and official committees. The first and most urgent requirement will be the provision of food and shelter for the starving, the refugees and the destitute. Then will come medical care of the sick, reorganization of the social and medical services and the setting into motion of agriculture and industry. For all this planning there must be a headquarters staff, under which the technique of relief and its specialist problems will have to be worked out in detail by *ad hoc* committees from among Allied representatives. The administrative capacity and pooled resources of the world will be taxed to the utmost. Medicine has an important part to play in this humane work of relief, and what it can do is now being discussed. Doctors and nurses, it is obvious, will be wanted for medical relief. The planning and carrying out of nutrition schemes, measures for the control of typhus, malaria, enteric, the danger of the present continent-wide increase in tuberculosis—these are but some of the tasks for international medicine in the postwar period.

In every one of the occupied nations, infant mortality rates are rising steeply and are said to be four times as high as they were in 1939. The edema due to starvation of protein is seen everywhere and degeneration of tissues due to deficiencies of vitamins is common.

The incidence of tuberculosis has increased from 30 to 80 per cent in different parts of Belgium.

In Great Britain a special advisory group has been established to advise the minister of health in relation ship to all these matters. In Washington today there are separate advisory medical groups for each of the many agencies. If there is any one need that confronts us now, it is the need for the establishment of a planning body representative of the best statesman like and medical opinion that the nation can offer to which may be referred the many problems of a medical character that are already arising as part of wartime and postwar rehabilitation. For Northern Africa, Italy and other medical rehabilitation are already under way. As France and Greece and Czechoslovakia and Poland and Belgium and the Netherlands are freed from the yoke of the aggressors, their people also must be provided with food, with medical and health supplies and with medical service. Every moment that is lost in confronting starvation or epidemic disease means more deaths and more disability. The medical profession of the United States is ready to join with leaders in every other phase of industry and professional service in planning suitable procedures for these conditions.

THE TREND OF AMERICAN MEDICAL PRACTICE

Thus far I have been concerned almost wholly with the extent to which the American medical profession and American medical resources will be used in aiding all of the postwar world with the marvelous professional skill and the vast quantity of superlative materials that American medical practice and American medical industry have developed. Of equal or greater significance to us in this country is the trend of changes in the nature of medical practice. During the twenty years that have elapsed since World War I the practice of medicine in the United States has been undergoing a continuous and rapid evolution. Many experiments have been initiated in wider distribution of the services of the medical profession and the hospitals. Nevertheless the fundamental features which have made American medicine the great profession that it is have been retained.

Do those who have gone forth to save democracy want to come back to the America, to the England or to the China that they knew or do they want a new world to result from this conflict? An advertisement which has caught the public fancy says in part:

Back home to the same town, to the same job you like so much, to the same America we have always known and loved where you can work and plan and build, where there are no limits on any man's, any woman's or any child's opportunity. That is the America I want when I come back. Don't change that ever. Don't let any one tamper with the way of living that works so well.

Every one of us wants to save all that was good in preglobal war America. We want, above all, the principle of freedom of choice and freedom of opportunity. The very basis of the American democracy has been that principle of free choice—free choice of the school one attends, the newspaper one reads, the church in which one worships, the store in which one purchases, the hospital in which one receives hospital care, the physician, the dentist or the lawyer whom one consults. Beyond such free choice is of course, the most fundamental of all freedoms for all men—freedom from want. Much has been said of the Beveridge and similar plans as a Magna Charta for the postwar world.

The primary concern of the Beveridge plan is freedom from want for the British people. In the United States freedom from want means a job with an income sufficient to enable the worker to provide himself with food, fuel, clothing, shelter and medical care. On the technique by which the work is to be guaranteed these fundamentals of living there has been much debate and disagreement. The technique by which security is provided may mean destruction of the freedoms that are basic in a democracy.

While there has already been a tendency to compare the report of the National Resources Planning Board to the Beveridge report and in fact even to dismiss the former by citing it in American Beveridge report, the contrast in the point of view is so striking as to be easily manifest to any one who reads carefully. The Beveridge report implies a state controlled medical service with the ultimate disappearance of the private practice of medicine. The American statement calls for cooperation between the medical profession and the government and an exploration of the potentialities of expansion of publicly provided medical care and also of the feasibility of methods such as social insurance. Now social insurance does not necessarily mean, I take it, compulsory sickness insurance and a state controlled medical service but equally the variety of plans developing now in many places as part of the American plan. The proposals in the report of the National Resources Planning Board for better coordination of medical and health facilities, for increased use of clinics, health centers and group practice where feasible, and for extended use of the medical technical service are certainly not officially opposed by American medicine. Most encouraging also however is the statement on page 459 that recognizes the fundamental principle that democracy is best maintained when the worker remains in control of his own funds. Here is the statement:

Experience has shown that the provision of economic security in the form of cash payments is not only greatly preferred by the recipients and thus a factor contributing to the maintenance of initiative and self respect but is also often more economical to the community.

American medicine recognizes its obligation. This conference has served to place before all of us the imminent threat of new post war medical problems. We shall study those problems, we shall plan, we will meet the obligation inherent on us to provide our people with the quality of medical service that has given us the lowest sickness and death rates in the world.

The problem has concerned equally the leaders in the field of medical care in Great Britain. Thus Viscount Dawson of Penn, discussing medicine and the public welfare wrote in May 1942:

There are few callings in which there is so big a gap between routine and the best work as in medicine, and no profession needs to be so elastic in its government if it is to be dynamic, not static. Its front line of knowledge is always mobile and often advancing; the men working there need freedom for initiative and should be unfettered by the formulae of administration and may be on the other hand, by the demands of practice. And the same considerations hold in the sphere of clinical practice for though we need ordered planning we must strive to avoid any cast-iron uniformity. Rather do we seek unity amidst diversity for man whatever his political colour, is individual and in illness even more so than in health and his doctor must remain an individual and not become an official. It is here that medical planning is up against its crucial difficulty in that it requires collectivism for its fabric and individualism for human relationships. And individualism will not flourish easily within the rigid boundaries

of a state service but needs the freer atmosphere which belongs to the voluntary hospitals' tradition, for in the difficult conditions of a greatly changing world doctors will need not only knowledge but understanding if they are to guide bodies and minds along the straight road of health and content.

This may well define the trend in the evolution in medical practice which we have been undergoing in the United States since 1935. Prepayment plans have been developed according to a variety of contracts. The plans developed have been modified according to circumstances especially prevailing in various areas. The individual participates in the plan of his own volition after he has been shown the evidence of the desirability for the plan and its utility for him and his family. The physicians who participate do so because they wish to be affiliated with the service—not because some all-embracing octopus-like compulsive mechanism placed on the people by the state has made it impossible for him to function as a physician without enrolment in a state-controlled procedure. In a nation like ours with wide diversities of population and industry and agriculture with a remarkable swing between per capita wealth and per capita poverty, the functions of the federal government may well be utilized toward making certain that all of the people have opportunity for suitable security against unanticipated illness. The medical profession has recognized the necessity for cooperation between the national, state and local governments with the forces of medicine, public health and welfare in the solution of these problems. However, medical decisions in matters of medical care must be made by medical men or there can be no safety for the patients. When medical decisions are controlled by economic considerations, the medical profession must have a voice in those economic factors. As the jobs and the funds available to our workers have become more profuse, workers in great numbers have abandoned sources of free and part-pay medical care to seek out their own physicians. Could there be any better evidence than the records of our hospitals, clinics, dispensaries and eleemosynary medical institutions to prove that the American worker wants to be free in the choice of his medical care?

By their own initiative the physicians of this country will have offered to the nation by 1944 the services of more than fifty thousand doctors (more than one third of all the active practitioners available in this country) to meet the nation's needs in time of war. By their own initiative they seek to give to the postwar world the most that American medicine can give for the restoration of the peoples of the world to health and physical fitness. They do not hesitate in offering themselves, they have been trained in the traditions of American medicine, which say to the doctor:

A profession has for its prime object the service it can render to humanity. The practice of medicine is a profession.

No greater task has ever confronted the physicians of America than the part they will be asked to play in the planning of medical services for the postwar world. They will meet that obligation as they have met every other call placed on them in the past—voluntarily, bound only by the traditions of their great profession, uncompelled by any arbitrary mechanism such as that founded by totalitarian governments to enslave both their people and the physicians who served them.

Clinical Notes, Suggestions and New Instruments

CONTACT DERMATITIS FROM OLIVE OIL

RICHARD L. SUTTON, JR., M.D. KANSAS CITY, MO.
Assistant Professor of Dermatology, University of Kansas
School of Medicine

Olive oil, *Olea europaea sativa* (*Oleum olivae*, U. S. P.), is generally believed completely bland on topical application. Many a dermatologic prescription contains it. I have, however, observed trouble resulting from its use. When it is applied to "dry scalp" (seborrheic dermatitis of the scalp) the dandruff is regularly made worse. When it is applied to senile pruritus the result is often unfavorable. Olive oil is not different from any other greasy substance when applied to superficial, vesiculating, automuculable, staphylococcic dermatitis, generally known

Contact dermatitis of ten years' duration due to olive oil

as "infectious eczematoid dermatitis." In this condition any unguent smears the parasites about, prevents their drying and promotes spread of the disease.

In the case which I report here the dermatitis was present for more than ten years and its maintenance was evidently due solely to olive oil, for interdiction of its use was followed by prompt cure. As I have emphasized previously, the cure of contact dermatitis is a matter of what is kept off the skin, not of what is put on it. It is an error to try to make the skin heal when the purpose should be simply to allow the skin to heal.

REPORT OF CASE

Miss M. W., a white woman aged 62, a housekeeper, came to the outpatient department of the University of Kansas Hospital on Dec. 27, 1939 because of scattered patches of shallow, scaly dermatitis. It had started more than ten years previously with a few lesions about the right knee, to which she applied olive oil. For ten years she religiously anointed the slightly itchy eruption with this substance and claimed relief by its application. Blood studies, showing slight secondary anemia

1. Sutton, R. L., Jr. Dermatitis Venenata. Practical Aspects and Innocuous Treatment, J. Kansas M. Soc. 40: 235-239 (Aug.) 1939.

but no abnormality of consequence and the absence of lymphadenitis and the biopsy revealing only chronic inflammation with parakeratosis suggestive of parapsoriasis supplied evidence that premalignant mycosis fungoides might be eliminated and that diagnostic possibilities among the rare and recalcitrant dermatoses were unlikely. The scalp was free from seborrheic dermatitis. There was no story of ingestion of drugs. No medication other than olive oil had been used. Therefore she was ordered to stop applying olive oil and to do nothing further about her disease. On Jan 24, 1940 she was seen and note was made that the eruption had faded and disappeared except for slight residual pigmentation. Objectively and to the patient's satisfaction she was cured. Treatment consisted of nothing at all, a regimen eminently suited to contact dermatitis in such instances as do not demand bland therapy designed merely to allay symptoms.

SUMMARY

A case of dermatitis of ten years' duration was due to the application of olive oil. In contact dermatitis what is not done to the skin is more important than what is done.

1102 Grand Avenue

A METHOD OF RESTORING NERVES REQUIRING RESECTION

WALTER F. DANDY, M.D., BALTIMORE

Delay in resuturing severed nerves always means that the resulting neuromas must be resected from the central ends and the peripheral ends freshened by a shorter resection. The end result of these procedures is to lengthen the gap between the two ends of the nerves. Under such conditions it is rarely possible to bring the two ends together at least without undue tension on the line of suture. At the elbow, for instance, the gap may be reduced by flexing the arm and holding it in position by a cast for several weeks. But such expedients usually end badly because subsequent straightening of the arm tears apart the line of suture of the inelastic nerves and good function is almost unattainable. In the upper arm and in the leg the ends of the nerve can be brought together only by freeing long segments of the nerve and even then, if united, the tension is so great that the suture line gives way and ends in loss of function.

It need hardly be added that direct end to end suture is the only method by which nerve function can be restored and, conversely, if this cannot be attained function of the affected nerve will be forever lost. The natural corollary of this statement is that all nerves should be resutured at the earliest moment compatible with the patient's general condition and infection of the wound in order to prevent the formation of neuromas. If nerves are sutured within the first few days after the accident, the ends can be brought together and all consideration of nerve lengthening avoided. Even in the presence of infection the nerves should be carefully sutured at once and with a very good chance of restored function—at least nothing is lost in the effort. When there is any doubt concerning the preservation of function and severance of the nerve, it is safer to assume that the nerve is cut and expose it at once rather than to assume that it might be intact and later find that operation and inevitable resection of the neuromas is necessary. The former assumption loses nothing, the latter probably means permanent loss.

In the first case here reported, the maximum test of nerve resuturing is presented. All the nerves in the upper arm were divided and when fifteen months later the neuromas were resected and the peripheral ends freshened there was an 8 cm defect between the ends of the nerves. It was possible to bridge this space only by shortening the humerus an equal amount; this was done by removing an oblique section of the humerus and wiring the ends. Shortening of the arm even to this extreme degree is probably of little concern, particularly with the function of the entire arm at stake. Although the long interval

between the time of the accident and that of the repair probably precluded a complete recovery, there was eight and one half months following the operation return of both motor and sensory function in all branches of the resutured nerves.

The same method can be used when a nerve is resected to cure a tumor along one of the nerve trunks in the upper arm or leg. When a tumor is removed with the nerve, the resection of bone should be done at the same time or within a few days thereafter.

CASE 1—History.—A girl aged 13 entered the Johns Hopkins Hospital on March 21, 1933 because of paralysis of the left arm following an accident.

Present Illness.—Fifteen months earlier a piece of flying glass cut the inner side of the left arm midway between the axilla and the elbow. She was exsanguinated and a transfusion was done. Several hours later the wound was closed by a

Fig 1—Operative sketch of case 1 showing resection of the four nerves in the upper arm and resuture of the nerves following removal of a segment measuring 8 cm from the humerus.

local physician who said he could find only one nerve which he sutured. The wound became infected and drained for a month.

Examination (Dr Frank Ford).—Fair flexion existed at the elbow but no extension, the triceps apparently being severed and knotted below the dense broad scar. The peripheral end of the triceps contracted but produced no extension, it pulled the scar. Pronation and supination were performed weakly. Extension and flexion at the wrist were lost and there was no action of the intrinsic muscles of the hand. Cutaneous sensibility was absent over the areas supplied by the median and musculospiral nerves; feeble sensibility existed over the ulnar, a pinprick being recognized as a stinging sensation. A biceps reflex was present, the radial and triceps reflexes were absent. The long flexors of the fingers and wrist supplied by the ulnar nerve reacted slightly to the faradic current and showed a prompt galvanic reaction. The remaining muscles

of the forearm and hand gave no response to faradism and only a slow contraction to strong galvanic stimulation. Apparently the ulnar nerve was the one sutured when the wound was closed and was now showing slight signs of regeneration.

There was a very feeble radial pulse. In the brachial artery a pulse could be obtained only in the axilla (the brachial artery

of the thumb or of the intrinsic muscles of the hand. There were some patchy areas of pain perception over the ulnar distribution.

Jan. 3, 1934, eight and one-half months after operation, she could flex and extend all the fingers with fair power. The thumb could be flexed and extended slightly. The wrist could be flexed, and there was beginning extension.

On the next examination, Jan. 10, 1943, ten years later, the elbow could be flexed and extended normally. The wrist could be flexed slightly and extended with more power. Pronation and supination were present in fair degree. There was no flexion or extension of the fingers, which were held in the flexed position. There was atrophy of the interossei and lumbricales. Sensation of all types was normal to the wrist. Below the wrist and over the entire hand and all fingers touch and sharp and dull pain were perceived accurately though less acutely than on the other side. Heat and cold were not recognized.

The end result therefore is good except for the hand and, despite early signs of returning function in flexion and extension of the fingers, these functions were subsequently lost. Sensory return was in all four branches, but to an imperfect degree in the hand. The case demonstrates that, even after a long interval of fifteen months, return of function can be obtained.

CASE 2—History—A girl aged 6 years was cut on the lower outer surface of the right upper arm by a pane of glass six months before. Wrist drop followed and had persisted unchanged, the radial nerve having been severed.

Operation—On Feb. 17, 1943 it was found that the nerve had been totally severed. A large neuroma was situated at the musculospiral groove and was resected, together with the upper end of the distant segment and the intervening scar. Three cm. of the lower end of the shaft of the humerus was removed by oblique incisions (fig. 2) and the ends were wired

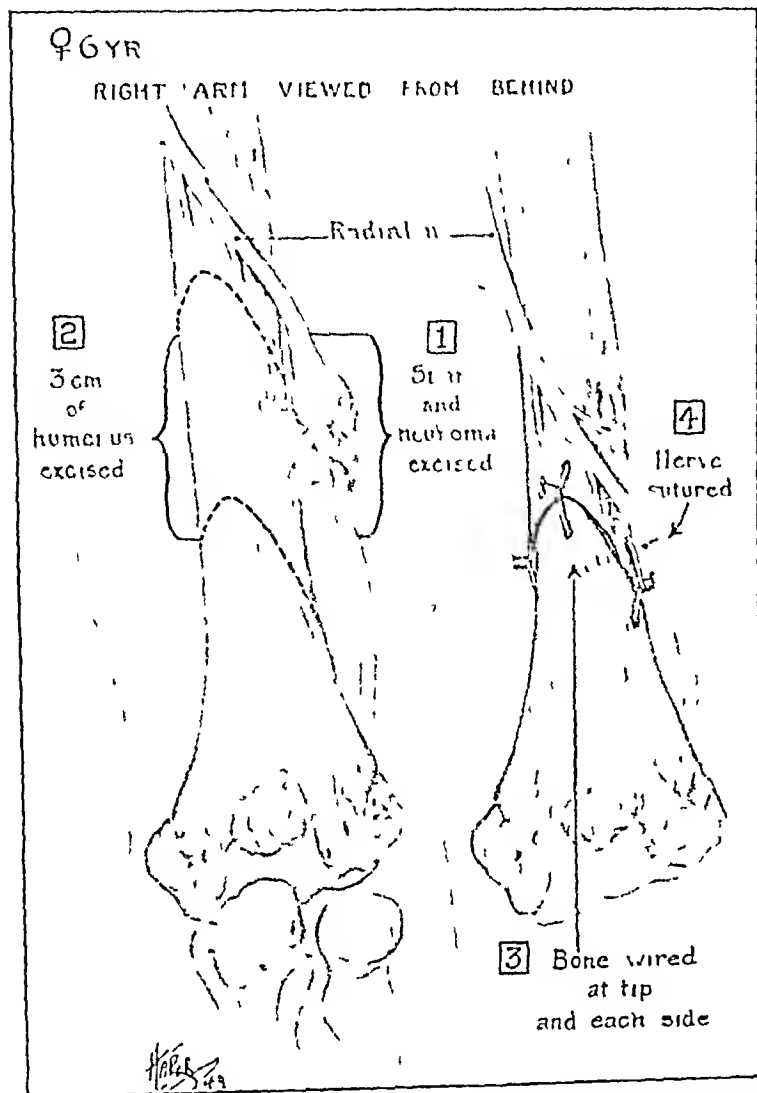

Fig. 2—Restoration of severed radial nerve following resection of 3 cm. of the humerus and an equal amount of neuroma and scar tissue from the nerve. The bone was wired by three sutures extending only through the cortex.

was severed at the time of the accident and was responsible for the severe bleeding).

Operation—March 22 the nerves of the upper arm were exposed and dissected above and below the scar. On each of the four big nerves—ulnar, median, musculospiral and musculocutaneous—there was a large neuroma, and all of these blended together into a mass of scar tissue. The peripheral ends of the nerves also entered into and fused with the scar. It was difficult to understand how even the minimal sensory function in the ulnar region could have been retained. After removal of the scar and the extensive neuromas from the central ends an 8 cm. defect (fig. 1) remained between the central and the peripheral ends of the nerves. This had been anticipated when the operation was begun. The only conceivable way to overcome this defect and make an end to end nerve suture was to resect the humerus. Accordingly an oblique section of bone 8 cm. wide was removed from the upper half of the humerus by an electric saw and the surfaces of bone were then wired. The humerus therefore was shortened 8 cm. The four nerve trunks were then sutured end to end without tension. The brachial artery was attenuated and a solid cord thrombosed. The triceps muscle was resutured. Healing was by first intention.

Subsequent Course—October 24, exactly six and one-half months later, the patient was able to flex the fingers and wrist, but extension was not possible and there was no movement

Fig. 3 (case 2)—Appearance of humerus after shortening 3 cm.

by three small sutures through the cortex only (fig. 3) instead of longer wires around the periphery.

Since the operation has been performed only two weeks, no report on the return of nerve function can be made.

This operative attack is of course applicable to severed nerves in the forearm and leg. It is the only way that function can be restored after an interval.

Johns Hopkins Hospital

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT: HOWARD A. CARTER, Secretary

MASSACHUSETTS VISION TEST ACCEPTABLE

Submitted by the Commonwealth of Massachusetts Department of Public Health, Division of Child Hygiene, 75 Tremont Street, Boston

Distributor: Welch Allen Company, Auburn, N. Y.

The Massachusetts Vision Test is a method of school vision testing which provides for the screening of children to determine the need of detailed ocular examination and possible treatment. A notable feature of the test lies in the fact that it can be applied to young children. Five and six year old children needing ocular attention can be detected when the test series is applied by those skilled in the handling of young children. Errors which occur in the testing by nonprofessional persons are said to result in more children being referred than actually require correction by the specialist.

The test series is composed of three parts.

Part One screens out cases of low visual acuity. The charts are constructed to minimize the possibility of memorization. Illumination of the charts is standardized. The Snellen Illiterate I is employed throughout because of the variation in difficulty between different letters and different numbers.

Part Two detects those who may pass the visual acuity tests but who have a hyperopic error which is latent and may require correction.

Part Three indicates cases in which there is difficulty in using the two eyes together.

The equipment provided for testing includes:

Illuminator—Equipped with two tubular light sources which provide satisfactory illumination over the surface of the Snellen chart. In establishing the standard of proper illumination an especially designed instrument was evolved by the manufacturer.

Snellen Chart—A card divided into four rectangles. The upper two rectangles each contain two lines, one with a 20/20 rating (20) the other a 20/30 rating (30). The third rectangle contains two lines of symbols, one with a 20/40 rating (40) and the other a 20/50 rating (50).

Within the fourth rectangle are three symbols of different sizes with ratings designated.

Occluders—A supply of clean square pieces of stiff paper or cardboard measuring $3\frac{1}{2}$ by $3\frac{1}{2}$ inches to be used by the examiner for covering the eyes. (These may be prepared in the class room beforehand and should be disposed of after use in each case.)

Plus Sphere Test—A pair of ordinary spectacles marked +1.50 for use in third grade and above. The lenses should be cleansed after each using with soap and water. (A second pair marked +1.75 is provided for use with children in the kindergarten and the first and second grades. The frame is of a lighter color to distinguish it from the spectacles used for the older children.)

Maddox Rods—Two pairs of spectacle frames containing no lens for the left eye and a small black disk with a central red ribbed glass section for the right eye. In one pair the ribs are vertical in the other pair horizontal. (Smaller pairs of frames are provided for use with children in the kindergarten and the first and second grades.)

House Chart—A wall chart showing a picture of a house with an opening in the window through which a small electric light bulb is inserted.

Pinhole Test—A small black tube with rectangular front section containing a pinhole opening and a cord attached at one corner. A perforated picture is affixed over the pinhole opening. A small electric light bulb is inserted in the tube to provide a point light source at the pinhole aperture.

In the instruction booklet for the test it is recommended that the testing be done in a room in which a 20 foot distance between the child and the test charts is available. Since the illumination for the tests is supplied electrically, window light is neither necessary nor desirable. A wall as far away from windows as possible should be chosen. Window shades should be drawn so that beams of light do not fall near or on the charts. (The room need not be completely darkened but a minimum of light will facilitate execution of the tests. Additional covering may sometimes be necessary to eliminate patches of light.)

The following directions for the test are taken from the instruction booklet:

Place the Snellen chart and the house chart side by side so that the center of each is about 40 inches from the floor. Arrange the electrical attachments in such a way that the illuminator, the lighted house chart and the pinhole test can be used in sequence.

Measure a 20 foot distance on the floor from the charts to establish the position at which the child is to sit while being tested. A table for holding the test materials and for recording results is placed to one side of this position. If a light control switch is provided it should be placed on the table within easy reach of the tester.

The tester sits with the back toward the charts, facing the child, so that squinting, pecking or turning the head can be observed and corrected. A separate desk copy of the Snellen chart is provided so that the teacher need not watch the wall chart while testing.

In the Council's examination of the unit it was found that light meter tests of the illuminated vision chart showed 11 foot candles at the top and bottom of the chart and approximately 6 foot candles in the center.

The arrangement of the distance vision chart expedites rapid and reasonably accurate elimination of eyes with approximately normal vision. The test letters (illiterate E's) are arranged in four groups with different colored borders. Each group consists of two lines. The upper two groups each contain a 20/20 and a 20/30 line of test letters. The lower two groups contain letters ranging from 20/40 to 20/100. The use of plus 1.50 spherical lenses in a spectacle frame roughly enables the examiner to eliminate the lower hyperopias.

The muscle test is based on the assumption that vertical phorias of more than 2 prism diopters and lateral phorias of more than 5 prism diopters potentially necessitate further examination and possible treatment. The near test, which is especially adapted to horizontal phorias, might be dispensed with if time is limited.

The Council reached the following conclusion concerning the apparatus:

1 It is a relatively simple and complete test, especially adapted for school children of the lower grades. Distance vision with elimination of lower hypermetropias and myopias as well as muscle balance are roughly measured.

2 It is purchasable as a single unit which increases its desirability for schools and factories.

3 In this test the same distances are customarily used for measuring vision and muscular anomalies which are employed in office and hospital practice. Thus it differs from stereoscopic tests.

4 The instrument is apparently a pioneer in grouping several fundamentals into a single unit adapted for mass testing of visual function by nonmedical examiners.

The Council on Physical Therapy voted to accept the Massachusetts Vision Test for inclusion on its list of accepted devices.

PLANNING FOR POSTWAR MEDICAL SERVICE

This issue of THE JOURNAL is devoted largely to publication of the papers read before the National Conference on Planning for War and Postwar Medical Services which was held in New York in March. Readers of THE JOURNAL will note that these papers provide a consideration of the problems of disease and nutrition which are likely to confront the postwar world, problems of personnel and materials and methods of administration of medical services. The purpose of that conference was to place on the table many of the questions which are now in the minds of those who are familiar with these subjects. The conference did not attempt nor did it propose to offer any plan for changing the nature of medical practice in the United States or for meeting world needs.

Any one with foresight realizes that there will be great changes in the postwar world. The medical profession does not fear change regardless of the aspersions of those who constantly assail it as a reactionary and too conservative group. For many centuries the medical profession has adjusted itself to the tremendous changes wrought by new discoveries and techniques in the prevention of disease and in the care of sickness, why should it be apprehensive regarding additional changes? The medical profession does realize, on the basis of many years of scientific observation, that change in itself is not necessarily beneficial. There may be change for the worse as well as change for the better. Trained in the scientific method, the physician studies his case and changes his treatment to meet new signs or symptoms, keeping in mind always the aphorism to hold fast to that which is good.

Before the people and the medical profession of this country there are now at least two formal proposals for development of medical care as part of national programs of security. The fundamental tenets of the

Beveridge plan have been widely reported in the public press, and the considerations of the Beveridge plan in Great Britain have been reflected by the correspondence from London in THE JOURNAL. On March 31 a special session of the representative body of the British Medical Association considered some proposals from the council of that organization relative to participation by the association in meeting the desires of the British government relative to the Beveridge plan. The council of the British Medical Association had indicated its belief that complete medical participation should be dependent on adoption of the Beveridge plan as a whole. Apparently it was feared that the medical aspects of the plan would be thrown to the British people as a "sop." Moreover, the council of the British Medical Association felt that the medical profession would be definitely opposed to a complete system of state medicine but would be willing to participate in a plan for medical service for all, provided physicians would be given opportunity to practice privately and participants in the plan would be given opportunity to seek private medical care for which they would pay out of their own funds. The results of the deliberations of the representative body of the British Medical Association are not yet available. In the meantime, however, it seems that the Parliament is proceeding to give special consideration to the medical proposals with the idea of making the beginning on the Beveridge plan with medical services exactly the "sop" that the British Medical Association must have anticipated on the basis of previous performances by political minds. Here in the United States representatives of American business and the other professions have begun to realize that the tossing of medicine as a "sop" to the proponents of state medicine is merely a concession which does not delay but rather gives impetus toward complete socialization and destruction of private enterprise.

The report of the National Resources Planning Board, which the President of the United States sent to the Congress in February, was hailed as an American Beveridge plan. Actually the National Resources Planning Board was established under President Hoover and most of the report was available more than a year before it was sent to the Congress. Those sections having to do with the medical phases of security had been published in pamphlet form in September—before the Beveridge plan had been made public. A recent Gallup poll indicated relatively little awareness by the American people of the content of the report of the National Resources Planning Board and indeed relatively little interest in the report. Most of the discussions concerning it seem to be appearing in periodicals like the *New Republic*, the *Survey Graphic* and the *Nation*, devoted to "little groups of serious thinkers." The report does not deal with details, it consists largely

of generalizations which incline toward the general point of view that action toward advancement of the health of the nation proceed along the following lines

(a) Health measures and adequate nutrition in order to eliminate all diseases disabilities and premature deaths which are preventable in the light of existing knowledge, through

1 The development of adequate public health services and facilities in every county within the country

2 The development of a health program for mothers and children ensuring remedial treatment as well as diagnosis and advisory services, maternal and child health clinics, and health services in the schools

3 Protection of workers whether in the factory or on the farm from unnecessary accidents, controllable occupational diseases and undue fatigue

4 Continued support from public and private funds for public health research and education with a view to the progressive expansion of the frontiers of control over health hazards

5 Continued support for public and private agencies engaged in the dissemination of knowledge of sound nutritional principles and practices. Especial attention should be devoted to demonstration work in the schools, the factories and farming areas

(b) Assurance of adequate medical and health care for all, regardless of place of residence or income status and on a basis that is consistent with the self respect of the recipient, through

1 Federal appropriations to aid states and localities in developing a system of regional and local hospitals and health centers covering all parts of the country

2 Assurance of an adequate and well distributed supply of physicians, dentists, nurses and other medical personnel

3 Expansion and improvement of public medical care for needy persons through larger appropriations and through increased cooperation by and with the medical and dental professions

4 Immediate action by government in cooperation with the medical profession to formulate plans which enable the patient to budget expenses over a reasonable period and to contribute toward the costs of care according to his ability and which at the same time assure to medical personnel a decent livelihood commensurate with the high costs of their professional training

The mark of intelligent man as contrasted with the higher apes is ability to plan for the future. On the medical profession primarily rests the obligation for much of the active work of reconstruction and rehabilitation of the postwar world. For such work the medical profession must begin to prepare now. Intelligent man does not repeat the mistakes of the past. Surely we would be unintelligent if we did not do everything in our power to meet our obligations so that the world would not again be faced by the disaster and catastrophe that followed World War I. As President-Elect James E. Paullin said in opening the National Conference on Planning for War and Postwar Medical Services, "The organizations we represent are composed of people who are willing to begin now to see that all of their personnel and scientific facilities are made available to help win this war, we are equally anxious that our talents, scientific achievements and services be made available to all nations and all peoples in planning for postwar medical service, not only to our own country, but to the countries of our allies and to the oppressed of the Axis dominated and controlled peoples

In his opening remarks at the banquet Mr. Basil O'Connor, president of the Finlay Institute of the Americas and of the National Foundation for Infantile Paralysis said in part

The prevention of disease, the promotion of health, the determination of nutritional deficiencies, the provision of food and of medical and health supplies and of trained scientific personnel are problems which already confront our own people and those of other nations of the world

The question of medicine and health will, of course, be a part of postwar relief in general, but it should not be submerged in postwar relief or confused with postwar reconstruction. Postwar health problems in the United States need not necessarily be any part of postwar relief, and yet, postwar reconstruction in other countries in so far as it relates to health and medicine may have a very direct bearing on postwar health problems in the United States

The subject of postwar health problems, both at home and abroad, is sufficiently enormous in itself to be kept separate and distinct from other postwar activities for the moment at least. Of course, postwar health activities must synchronize with postwar reconstruction, but they must not be considered secondary

Just a month ago, Melville MacKenzie, principal regional medical officer of the British Ministry of Health, made the following statement

"In the three years following the last war, more people died from famine and preventable diseases than had been killed in the war itself, and their deaths were largely the result of administrative chaos in relief"

I think we all admit the existence of the problem. I think we all are cognizant of its seriousness. I think we all are aware of the difficulties involved in its administration, and I know that we all are fully aware of the necessity of preparing to meet it now

Every moment that is lost in confronting the threat of epidemic disease or of starvation, either at home or abroad gives these horsemen of the Apocalypse greater speed in their carrying of death

From the papers published in this issue of THE JOURNAL and from the considerations here presented, it is apparent that postwar planning for medical services is a subject sufficiently large and important to demand the best thought and consideration that our nation can afford. In meeting these problems there should be no piecemeal planning, the problems must be considered as a whole. The programs adopted in medical rehabilitation of the occupied countries and the action by the British Parliament on the medical aspects of the Beveridge plan are likely to affect seriously the nature of medical practice in our own country. The nutritional problem of the world is dependent for its solution on scientific diagnosis of nutritional deficiencies. The provision of medical personnel of all kinds adequate to meet the needs of the postwar world will throw a tremendous burden on American medical education. Certainly the time is not too soon to suggest that the government of the United States establish as soon as possible a mechanism for giving to these questions the analysis and consideration that they deserve and for suggesting the steps that may be followed under a democratic government for their solution

EXTRAHUMAN SOURCE OF
POLIOMYELITIS

Virus infected rodents may be the source of outbreaks of human poliomyelitis, according to a recent report by Jungeblut and Dalldorf¹ of Columbia University. Five cases of poliomyelitis occurred during September and October 1942 within a sharply circumscribed half square mile area in White Plains, N. Y. The cases occurred in rapid sequence and were the only cases of poliomyelitis reported in White Plains for over a year. Two cases, however, had occurred in the same restricted area during the previous year. The 1942 epidemic involved 2 adults and 3 children, of whom 2 died of bulbar paralysis while 3 recovered with extensive peripheral paralysis. Microscopic study in the 2 fatal cases revealed severe and typical poliomyelitis lesions of the cord and medulla.

In the search for possible extrahuman sources of this epidemic a dead gray house mouse, which obviously had been dead for only a short time, was discovered in the basement of the home in 1 of the fatal cases. A second gray mouse was trapped in the same basement. Additional house mice, dead or alive, were collected in other parts of the epidemic area. Ten per cent saline suspensions were prepared from the glycerated brains of these mice and injected intracerebrally into white mice. Definite symptoms were observed in white mice injected with three different suspensions: one prepared from the dead mouse, one from the trapped mouse found in the house and one from another mouse trapped in the immediate neighborhood.

In the injected mice characteristic prodromal symptoms appeared after an incubation period of from five to fourteen days progressing in some animals to a fatal paralysis of both front and hind legs. The infection thus far has been propagated through twelve serial passages from these fatal cases. By the third serial passage the virulence was considerably increased so that it now became infectious for hamsters and cotton rats, in which it produces a typical prostrating paralysis. Cultural tests showed that all serially infected brains were bacteriologically sterile. The infectious agent was readily passed through a Seitz filter.

In the fully developed paralytic disease in white mice microscopic examination revealed extensive destruction of the anterior horns in various levels of the spinal cord similar to the clinical picture of "rodent poliomyelitis"² and of mice paralyzed with the mouse adapted Lansing strains of the human virus³. The serums from 2 of the 3 local convalescent patients neutralized this virus *in vitro*. From such evidence the New York investigators concluded that the dead and trapped mice of the local

area were presumably suffering from the same virus infection as the human patients.

Confirming this conclusion, Jungeblut tested the mouse infectivity of the brain and cord in the 2 fatal human cases. Intracerebral injection of the material from 1 cord caused a prostrating paralysis with typical lesions in 1 monkey. The cord material from this monkey caused death in a hamster on the twentieth day, from which point on the disease was readily transmitted serially in both hamsters and mice by either the intracerebral or the intraperitoneal route. This passage virus was neutralized with poliomyelitis hyperimmune horse serum and also with the 3 convalescent human serums from surviving patients. The viruses isolated from the dead house mouse and from the fatal human cases were therefore apparently identical in specificity and differed only in relative virulence. More detailed studies are now in progress.

The observations of Jungeblut and Dalldorf may well constitute one of the most important contributions to the epidemiology of poliomyelitis of the present decade since it is the first time that a probable extrahuman source of human poliomyelitis has been supported by experimental evidence. Faber's⁴ recent demonstration of the hypersusceptibility of the oropharyngeal surface to virus of poliomyelitis adds to the concept of human poliomyelitis as a mouse borne food infection.

REFRIGERATION (CRYMO-) ANESTHESIA

Future generations may find it difficult to understand why it is taking us so many years to appreciate the significance of reduced temperature. Little thought has been given to temperature physiology by most of us, except for rather empirical fever observations. Attempts are still made to keep tissues at "normal" temperature in spite of the rebellion of many patients with peripheral vascular disease. The usefulness of maintaining life processes at a reduced rate by lowering the temperature is still not generally understood. Perhaps this is due in part to the erroneous tradition that external heat should always be applied for the prevention and treatment of traumatic shock.¹

Recent reports indicate that in combat areas military surgeons are largely occupied with the care of injuries of the extremities. The older methods of anesthesia for these cases are not completely satisfactory. In minor cases general anesthesia frequently seems out of proportion to the primary condition, and in severe cases the added burden may be dangerous.

Life processes, in common with chemical reactions, have a speed which is profoundly influenced by temperature. Oxygen consumption of the tissues can be reduced about 13 per cent for each degree centigrade

When a tourniquet is applied and the extremity is packed in ordinary clipped ice (without salt) the oxygen demands are reduced sufficiently to prevent necrosis for many hours. The skin temperature falls to 2 to 4 C and surgical anesthesia is complete within about two hours.

This method should not be confused with placebo freezing with ethyl chloride spray which is quite unsatisfactory and objectionable. True refrigeration anesthesia was first used for amputation of partially gangrenous extremities of patients in the older age groups.² There has been caution in applying it to traumatic cases.³ Refrigeration without a tourniquet is useful but not completely anesthetic.⁴ Refrigeration with a tourniquet affords surgical anesthesia and does not of itself require amputation.

If it is necessary to demonstrate the presence or absence of circulation in tissue of doubtful viability, the tourniquet can be loosened, but this results in loss of anesthesia as soon as the tissues are warmed. The manufacture of sterile ice is neither difficult nor expensive with proper equipment it can be made by medical units in the field.

Each anesthetic method has its own difficulties and disadvantages. Cooling inhibits or delays inflammatory reactions and the autolytic changes that are familiar as the gross evidence of gangrene.⁵ Failure to appreciate these refrigeration phenomena may lead to misinterpretation of the true nature of the situation and faulty management.

Theoretically, one might expect that the tourniquet and refrigeration would increase the dangers of post-operative sloughing. Practically, it has been found that the factors of safety in this respect are quite adequate even in the presence of arterial disease. Actual experience with the procedure convinces surgeons, internists, nurses and especially patients that it is a far more conservative and sensible anesthesia than the commonly accepted methods.

Refrigeration offers advantages for nearly all cases of severe wounds of the extremities. Prevention and treatment of shock may be sufficient indication, surgical anesthesia is a valuable by-product. The suffering and blood loss from periodic loosening of an emergency tourniquet can now usually be avoided. Certainly external applications of heat should never be used in conjunction with a tourniquet. Simple measures can and always should be instituted to help cooling whenever a tourniquet is applied. This is especially important in hot environments.

The large scale program of medical education for war which is now in progress should include instruction

in temperature physiology and advanced courses in the principles and practice of refrigeration anesthesia. Anesthetists should not cloister themselves in the surgery and devote their lives to the dogma and rituals of the past. These subjects must be made known to all.

Current Comment

WHAT THE PUBLIC KNOWS ABOUT HEALTH

A report of a "quiz corner" study¹ carried out at the New York and San Francisco world fairs gives positive information about the knowledge of the average person regarding health. These quiz corners were placed where visitors to the fairs would pass them in large numbers. The tests were based on two hundred and twenty-three test questions covering cancer, communicable diseases, nutrition, general health information, superstitions and misconceptions, anatomy and physiology, maternal and child health, venereal diseases and tuberculosis. These were divided into five tests of twenty-five questions and two tests of fifty questions each. Some questions that fell in several categories or were repeated with different emphasis were included in more than one test form. The results of this extensive test of approximately a hundred thousand people did not develop anything startlingly new. Certain facts were established which, at least for the newcomer to the field of health education, should save needless and costly blundering. Health knowledge differed little between New York and San Francisco. In both places persons who had traveled farthest to see the fairs made better scores, being presumably somewhat better off economically and having therefore enjoyed better educational opportunities, wider experience or both. A difference in wording affects the response. For example, faced with the statement "Tuberculosis may be inherited" and a true-false choice, 45 per cent at the New York fair and 47 per cent at San Francisco indicated their belief that tuberculosis was inherited. This looks almost like a chance answer. When, however, the same information is called for in a multiple choice type of selection, namely, "Which one of the following conditions is inherited? (a) tuberculosis, (b) color blindness, (c) syphilis," only 10 per cent of the New York group and 14 per cent of the San Francisco group chose tuberculosis as the inheritable condition. These were not the same groups of people but they were groups in each instance approximating five thousand, except the San Francisco group of ten thousand of which 47 per cent indicated that tuberculosis is inherited. Other predictable results were that health workers made the highest scores, while workers in other professions tended to be above the general average. Housewives knew more about nutrition and older people knew more about the problems of older persons while younger people were more familiar with problems appropriate to their own ages.

PHARMACOPEIA ADDS MULTIPLE VITAMIN COMPOUNDS

Shortly after the establishment of the therapeutic importance of vitamins, the United States Pharmacopeia undertook to provide standards and assay methods. At first the action of the Pharmacopeia was confined to individual vitamins, when the U. S. P. XII appeared in 1942 then employment in combinations similar to those found in foods was so thoroughly accepted by medical authorities that the Pharmacopeia found it advisable to provide recognition and standardization for an increasingly large number of these substances. The latest U. S. P. preparations of vitamins, the "Hexavitamin" (six vitamins) Capsules and Tablets, the "Triasyn B" (three synthetic B vitamins with liver) Capsules, Tablets and Injections, have all been approved by authoritative medical groups and were added to the Pharmacopeia at the request of the Office of the Surgeon General of the Army for special use among the troops. These forms of vitamin combinations are commonly sold as "Multiple Vitamins" for the "Hexavitamin type," and as the "B-Complex" for the "Triasyn B type." Neither synthetic pyridoxine hydrochloride nor calcium pantothenate was added to the "B-Complex" type on the recommendation of the National Research Council and the Council on Pharmacy and Chemistry of the American Medical Association since these compounds have not yet had sufficient clinical study to justify definite therapeutic claims. However, the new "Liver B-Vitamins Concentrate" and "Injection" and "Dried Yeast" and "Dried Yeast Tablets" were introduced to furnish elements of the B complex when these were needed. The U. S. P. Vitamin Advisory Board as now established has the following membership: Dr. C. A. Elvehjem, University of Wisconsin, Madison, Wis.; Dr. C. G. King, scientific director of the Nutritional Foundation, Inc., New York; Dr. E. V. McCollum, Johns Hopkins University, Baltimore; Dr. E. M. Nelson, Vitamin Division, Food and Drug Administration, Washington, D. C.; and E. Fullerton Cook, Philadelphia, chairman. The scientific standing of this board gives assurance of careful scientific evaluation.

MUDDY THINKING IN NEW YORK TIMES ABOUT COMMISSIONS FOR WOMEN PHYSICIANS

The peculiar confusion of thought which characterizes practically all editorials in the *New York Times* on medical subjects is especially emphasized in a statement published in that newspaper on April 22 with the title "Women Army Doctors." After announcing the fact that the Congress passed legislation authorizing the commissioning of women physicians in the Army and Navy medical departments for the period of the emergency, the editorial says: "There are at least 5,000 and possibly as many as 7,000 women physicians. Permit them to practice in base hospitals—all that the bill sanctions—and the drain on the country's medical resources would be less than it is." Since the country's medical resources consist of all the physicians that we have, and since the physicians are needed

in the armed forces, industry and civilian life, and since the conditions are just about equally critical in all three fields, just how is the drain reduced by moving women doctors who are practicing in civilian life into the Army? Obviously, removal of a woman from civilian practice merely creates another area in civilian life for which a physician has to be found. The confusion here illustrated is simply a matter of logic. When it comes to any consideration of the practice of medicine, the failure of the *New York Times* to secure information from authoritative, qualified sources is even more obvious.

COBRA VENOM FOR PAIN OF ARTHRITIS

Talkov and Bauer¹ report the results of daily intramuscular injections of cobra venom to 12 selected patients with rheumatoid arthritis. Three of the 12 patients experienced subjective relief estimated variably from 25 to 75 per cent. Improvement was not complete, dramatic or lasting in any case. Objective alterations were not detected. The only significant toxic effect was local reaction at the site of injection in 1 patient. The observed effects with large doses of cobra venom for control of pain in rheumatoid arthritis hence were disappointing and contrary to previous reports. These Boston investigators conclude that cobra venom is without value for the relief of pain associated with rheumatoid arthritis.

"B₁ VITAMIN HYPOIMMUNITY"

In *THE JOURNAL* for April 17, page 1284, appeared a report of recent research by Foster, Jones, Henle and Dorfman, an account of which was published in the *Proceedings of the Society for Experimental Biology and Medicine* for November 1942, which seemed to indicate that excessive doses of thiamine might seriously lower susceptibility to the virus of poliomyelitis. Dr. Joseph Stokes Jr., in whose department the work was carried on, now informs us that the brevity of the presentation on which the original editorial in *THE JOURNAL* was based no doubt led to some misinterpretations of the facts presented. Adequate data ruled out the specificity of thiamine in this connection. Thus later results show not only that the mice on a vitamin B₁ deficient diet have increased resistance over a period of thirty days to the Lansing strain of murine poliomyelitis virus but also that simple restriction of food intake will produce comparable results. However, increase of the concentration of thiamine in the diet so that the amount consumed by the animals on the restricted intake was at least double that of the animals on the unrestricted intake did not increase the incidence of paralysis or death. From the data it appears that restriction of the intake of either the complete ration or just the carbohydrate will delay the manifestation in mice of infection with the Lansing strain of poliomyelitis virus. The interpretation originally made is not warranted in the light of the complete evidence.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

SOLDIERS TO HAVE FREE LEGAL AID

Heretofore a soldier who needed legal advice went to his company commander, the post chaplain or the Red Cross representative. Under a new plan sponsored by the War Department and the American Bar Association, a commissioned officer who is also a licensed attorney is appointed the legal assistance officer at each post camp or station. The legal assistance officer will have the cooperation and help of volunteer civilian lawyers from nearby communities who have been chosen by the state bar association committee on war work for that purpose. The only barriers put on the aid offered is that the legal assistance officer may not collect debts, advise or assist military personnel who are or might be subject to court-martial investigation or charges, and he may not appear before civil courts, boards or commissions as attorney for the soldier or officer. All talks and dealings between military personnel and the legal assistance officer will be considered strictly confidential and personal. No superior officer may order disclosure of any information confided to the legal assistance officer. Free legal aid for all military and civilian personnel of Carlisle Barracks is now guaranteed under a recent War Department order authorizing the appointment of a legal assistance officer there. Capt. Henry E. White, post judge advocate, has been given this additional duty.

LAST OFFICER CANDIDATE CLASS AT CARLISLE BARRACKS

Two hundred and twenty enlisted men of the medical department became commissioned officers after graduating in the last officer candidate class at the Medical Field Service School, Carlisle Barracks, Pa., February 27. This made a total of 2,809 medical administrative officers who have been commissioned at Carlisle Barracks and sent to units to take over administrative work, thereby relieving medical and dental officers for duties requiring professional skill. In the future all medical administrative officer training will be conducted at Camp Barkeley, Texas, where the medical administrative school, opened about a year ago, graduates a thousand officer candidates each month. The closure of the officer candidate school at Carlisle Barracks was brought about by the need to increase the number of medical and dental officers in training for field duty at that station. Twenty-seven states and the District of Columbia were represented in the last class.

THE CITATION ACCOMPANYING GENERAL KENNER'S AWARD

THE JOURNAL on January 16, page 199, noted the award of the Distinguished Service Medal to Brig. Gen. Albert W. Kenner of the U. S. Army Medical Corps for distinguished service overseas. The War Department on April 7 made available the citation accompanying General Kenner's award. The citation read as follows: "Brigadier General Albert W. Kenner (then Colonel) United States Army. For exceptionally meritorious service in a position of great responsibility. General (then Colonel) Kenner organized the medical service of a Task Force accompanied that Force in the landings in French Morocco, and directed the operation of the medical service during the combat phases of the operation. When existing facilities at French Morocco were inadequate to care

for the number of wounded men, he obtained shelter and medical supplies and personnel to care for them. He personally supervised their care and as a result of his efforts only 2 out of 400 patients died."

THE DESHON GENERAL HOSPITAL

The U. S. Army Deshon General Hospital at Butler, Pa., was dedicated on March 26 in the presence of many guests from Washington, Baltimore, Harrisburg and other cities. Brig. Gen. Larry B. McAfee, assistant to the Surgeon General, gave an address entitled "The Life of George Durfee Deshon, Lieutenant Colonel, Medical Corps." Lieutenant Colonel Deshon, a native of Massachusetts, entered West Point from Dartmouth College and graduated in the class of 1886, of which Gen. John J. Pershing was a member. While stationed at Fort Wayne he began the study of medicine at Detroit Medical College. He resigned from the Army in 1890 and entered Bellevue Medical College, New York, for his senior year then reentered the Army as an assistant surgeon in 1892. Lieutenant Colonel Deshon is to be remembered especially for the part he played in the reorganization of the Medical Department in 1908 and for the planning and construction of Gorgas Hospital in the Panama Canal Zone.

The General Hospital which was named in honor of Lieutenant Colonel Deshon occupies the buildings formerly known as the Western Pennsylvania State Sanatorium for Tuberculosis. These buildings, erected in 1938 but never occupied, were taken over by the War Department and the hospital was activated on Oct. 26, 1942.

The remodeling of the buildings and the construction of new wards, mess halls, officers' and nurses' quarters and barracks, and of other buildings sufficient to enlarge the capacity to more than 1,000 beds was undertaken by army engineers. The new wards and barracks will be ready for occupancy within a short time.

The medical officers at present on duty at the hospital are:

COLONEL

Gentzlow, Cleon J., commanding officer

MAJORS

Arack, George, executive officer
Bettison, William L., chief of officers section
Bizzozero, Orpheus J., chief general medical section
Bovik, Leslie E., chief surgical service
Davis, Perk L., chief medical service
Farrow, Reginald C., chief orthopedic section
Governale, Vincent J., chief x-ray service
Smith, Arthur W., Jr., assistant chief surgical service
Stuart, Carroll W., chief maxillofacial surgical section
Uhler, Claude, chief neuropsychiatric section

CAPTAINS

Beck, Frederick W., assistant chief eye, ear, nose and throat section
Burnett, George W., chief contagious disease section
Drenckhahn, Charles H., chief gastroenterology section
Edwards, Jesse E., chief laboratory service
Ellis, Sydney, chief anatomic section
Epstein, Joseph, stationurgeon and admitting officer
Gaines, Reuben B., chief urology section
Nichol, Arthur D., assistant chief medical service
Sawicki, Herman H., dermatologist and hospital in pector
Schnebli, John T., chief eye, ear, nose and throat section
Tsloff, Nicholas M., registrar
Wadsworth, George H., chief general surgical section

FIRST LIEUTENANTS

Balsamo, Nicholas T., surgical ward officer
Conrad, Joseph W., medical ward officer
Davies, Baxter T., medical ward officer
Smith, Robert B., medical ward officer
Van Hale, Laurence A., surgical ward officer

CIVILIAN DEFENSE

CIVILIAN PHYSICIANS IN OCD-U S P H S
AFFILIATED UNITS TO GIVE ARMY
TEMPORARY LOCAL ASSISTANCE
IN MILITARY EMERGENCIES

Affiliated hospital units of physicians are being organized by selected hospitals and medical schools at the invitation of the Office of Civilian Defense and the U. S. Public Health Service to provide balanced medical staffs for emergency base hospitals in the coastal states. Emergency base hospitals are institutions in relatively safe areas to which casualties and other hospital patients may be transferred from casualty receiving hospitals in target cities under enemy attack. Members of the affiliated units receive inactive commissions as reserve officers in the Public Health Service and will be called to active duty by the Surgeon General only on the recommendation of the chief medical officer of the Office of Civilian Defense.

The affiliated hospital units will also be prepared to assist the Army in the event of an extraordinary military necessity in or near the localities in which these physicians reside, the Medical Division of the Office of Civilian Defense announces. This arrangement will relieve the Army of the necessity for organizing its own special groups of civilian physicians for local emergencies and will help to conserve the dwindling supply of physicians for the civilian population. Unit members have willingly accepted this new responsibility according to reports from OCD regional medical officers.

For the purpose of giving such temporary assistance to the Army, a unit will be activated on the advice of the state chief of Emergency Medical Service and will be relieved from active service as soon as the Surgeon General of the Army can handle the emergency by the assignment of army medical officers, the OCD pointed out. Nurses are being appointed in the Public Health Service so that they may be available for similar temporary duty in serious military emergencies. Nurses on such duty will be relieved as promptly as possible by the assignment of Army nurses. Army authorities will make all requests for medical and nursing assistance through OCD regional medical officers or through state chiefs of Emergency Medical Service who may have been designated as representatives of the regional medical officers.

The Board of Trustees of the American Medical Association at its meeting of Sept. 17-18, 1942, approved the formation of the affiliated hospital units. On March 20 the directing board of the Procurement and Assignment Service of the War Manpower Commission also gave full approval to the formation of the units to provide medical care for civilian casualties and other hospital patients who must be moved out of their communities of residence because of enemy action and to provide temporary care in extreme emergencies for military personnel in extemporized hospitals. The directing board pointed out that this arrangement safeguards civilian medical needs against hazardous withdrawal of physicians in an emergency.

The resolution adopted by the board urged state chairmen of the Procurement and Assignment Service to give every possible assistance to the organization of the units. It emphasized that applications for commissions will be accepted only from physicians 45 years of age or over, women physicians, physicians of any age who are physically disqualified for military duty and physicians already declared by the Procurement and Assignment Service to be essential for civilian needs.

Initially, only hospitals and medical schools in areas considered to be in most immediate danger of enemy attack were invited to establish units. The Army's request has now made it necessary to have similar groups in the interior regions to augment military personnel temporarily in the event of an extraordinary influx of military casualties. A few institutions in interior states have already been invited, but the entire list for these states has not been completed.

Because the units are to be used only in their areas of residence, the OCD and the Public Health Service have invited 191 hospitals and medical schools in various parts of the country to form affiliated units from their staffs. Up to April 19, unit directors had been nominated by 152 of these institutions and 104 had been cleared for commissions. In addition, appli-

cations had been received from 397 members of units. A unit consists of 15 members, including a chief and assistant chief of medical services, 2 general internists, a chief and assistant chief of surgical services, 4 general surgeons, 2 orthopedic surgeons, 1 dental surgeon, 1 pathologist and 1 radiologist.

First in the country to complete a unit was Albany Hospital, Albany, N. Y. Other institutions which on April 15 had substantially completed the membership of their units were

Newark Beth Israel Hospital, Newark, N. J.
St. Paul's Hospital, Dallas, Texas
Norwood Hospital, Birmingham, Ala.
Columbia Hospital, Columbia, S. C.
Baylor Hospital, Dallas, Texas
James M. Jackson Memorial Hospital, Miami, Fla.
Stanford University Medical School, San Francisco
Huntington Memorial Hospital, Pasadena, Calif.
San Joaquin County General Hospital, French Camp, San Joaquin County, Calif.
Syracuse University College of Medicine, Syracuse, N. Y.
Jewish Hospital of Brooklyn
Eastern Maine General Hospital, Bangor, Maine
Methodist Hospital, Dallas, Texas
Lynchburg General Hospital, Lynchburg, Va.
Springfield Hospital, Springfield, Mass.
Maine General Hospital, Portland, Maine
Central Maine General Hospital, Lewiston, Maine
Newark City Hospital, Newark, N. J.
Atlantic City Hospital, Atlantic City, N. J.
City County Hospital, El Paso, Texas
University of California Medical School, San Francisco

In the following institutions the organization is practically complete

FIRST CIVILIAN DEFENSE REGION

Eastern Maine General Hospital, Bangor
Central Maine General Hospital, Lewiston
Maine General Hospital, Portland
Springfield Hospital, Springfield, Mass.

SECOND REGION

Jewish Hospital, Brooklyn
Albany Medical College, Albany, N. Y.
Syracuse University College of Medicine, Syracuse, N. Y.
Newark City Hospital, Newark, N. J.
Newark Beth Israel Hospital, Newark, N. J.
Atlantic City Hospital, Atlantic City, N. J.

THIRD REGION

Lynchburg General Hospital, Lynchburg, Va.

FOURTH REGION

James M. Jackson Memorial Hospital, Miami, Fla.
Columbia Hospital, Columbia, S. C.
Norwood Hospital, Birmingham, Ala.

EIGHTH REGION

Baylor University College of Medicine, Dallas, Texas
St. Paul's Hospital, Dallas
Methodist Hospital, Dallas
City County Hospital, El Paso, Texas

NINTH REGION

Colles P. & Howard Huntington Memorial Hospital, Pasadena, Calif.
University of California School of Medicine, San Francisco
Stanford University School of Medicine, San Francisco
San Joaquin General Hospital, French Camp, San Joaquin County, Calif.

Many additional institutions have in process the organization of such units. These will be announced as arrangements are completed.

DR. PAUL W. DAVIS REPORTED MISSING

According to the Peoria Star, Dr. Paul Wilson Davis of Jennings, a suburb of St. Louis, and a first lieutenant in the Civil Air Patrol, has been missing since February 26, when he took off in a plane with an observer and with other planes as escorts to a convoy along the Atlantic coast. The planes became separated while patrolling. Lieutenant Davis radioed a distress message, but the other fliers and the Coast Guard after searching the area were unable to find any trace of the plane and its occupants. It is said that Mrs. Davis, the wife, and the young son in St. Louis were notified from Washington. Dr. Davis entered the Civil Air Patrol last September. He was serving both as a pilot and as base physician. He was born in Chicago in 1912, later lived in Peoria and graduated in medicine at St. Louis University School of Medicine in 1939. He had an internship at King County Hospital, Seattle, and a residency at Methodist Hospital in Peoria. He was in practice in Jennings before joining the Civil Air Patrol.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

Under the auspices of the American Medical Association the American College of Physicians and the American College of Surgeons a series of Wartime Graduate Medical Meetings is in process of organization. These meetings are authorized, as far as they concern the armed forces, by the Surgeon Generals of the Army, Navy and Public Health Service. The organizations concerned have appointed a committee of three men—one from each organization—to proceed with the work of administration. This committee includes Dr. Edward L. Bortz (chairman, 4200 Pine Street Philadelphia), Dr. William B. Breed (secretary-treasurer) and Dr. Alfred Blalock.

The Plan

For organizational purposes, the country has been divided into twenty-four sections and key committees of three men appointed in each section to carry on the details of the program. Likewise, to insure a most worthwhile program a group of qualified authorities has been designated to serve as national consultants in the various special fields.

The duties of the section committees are:

- 1 To be responsible for the details of programs at each service hospital in their respective regions, where programs are to be conducted.
- 2 To be responsible for the selection of teachers and speakers with the assistance of the central committee and of the national consultants.
- 3 To arrange time of meetings and schedules of travel and appearance of the teachers within their respective territories.
- 4 To furnish copies of the programs to the commanding medical officers of the hospitals (programs shall be mimeographed or otherwise reproduced by the hospitals themselves).
- 5 Supervision of expenses, which shall be limited to necessary travel costs, also the forwarding of statements of these to the secretary of the central committee, Dr. William B. Breed.
- 6 To obtain from the commanding officers at the end of the period of instruction a written statement concerning their impressions, and those of their staff, regarding the value of the courses, and suggestions for improvement.

The duties of the consultants are:

- 1 Each consultant to prepare a specimen six hour teaching schedule for a one day period.
- 2 To cooperate with the regional committees in working out local programs and securing the teachers.

When the teaching schedules have been prepared by the consultants and lecturers have assembled the programs will be submitted to the Surgeon Generals of the Army, Navy and Public Health Services and the commanding officers of the various army corps commands and naval districts. When the desire for courses is indicated, the details will be arranged through the local committee with the assistance of the key schedules and the appointment of speakers.

In states where postgraduate activities are already being extended in the direction of service hospitals, it will be the policy of the Committee for Wartime Graduate Medical Meetings to turn over requests that may come to it to the group which is already functioning. Furthermore it desires to cooperate in every way possible with committees of local or state medical societies.

The teaching schedule will include ward walks, clinics, practical demonstrations, moving pictures, lectures and conferences offered to medical installations throughout the entire nation.

In carrying out the plans of the committee no single pattern can be strictly followed. However, suggested methods of approach are herewith listed:

(a) Meetings such as those already held in Boston, Philadelphia and Chicago where lecturers addressed groups in various camps on successive nights or a one day meeting at a central point with several outstanding speakers embracing topics of vital interest.

(b) The organization of teams which may arrange to visit one or more camps in nearby areas to put on a one day and evening program. Such teams may appear at two or three adjacent camps on successive days.

(c) In areas where five or six service hospitals are within reasonable distance from a central distributing center, a complete six day postgraduate program may be offered on the following basis:

The organization of six teams of two or more authorities each, from different medical specialties, to appear at the five or six hospitals in that area, each team on one particular day for five or six consecutive weeks. The program may include teaching ward rounds and laboratory demonstrations for small groups in the morning hours. Motion picture exhibits and one lecture with a question and answer period may be presented in the afternoon and a further lecture, seminar or round table conference in the evening.

It is evident that any of the foregoing plans, all of which are tentative and illustrative only, might have to be modified to meet local conditions. However, teams of teachers should be available in the various medical concentration areas throughout the country to conduct full courses of instruction where needed. Also it may be expedient at occasional intervals to repeat this circular or peripatetic plan two or even three times a year, depending on the change of medical personnel in the service hospitals.

It is the desire of the organizations in charge to extend to the doctors in the armed services the best facilities of American medicine in the interest of our fighting men.

Committee for Wartime Graduate Medical Meetings

BOARD OF NATIONAL CONSULTANTS

- 1 Anesthesia—John S. Lundy, 102 Second Avenue S.W., Rochester, Minn.
- 2 Aviation Medicine—Lieut. Col. W. Paul Holbrook, M.C.U.S., Army Air Surgeon's Office, Headquarters, Army Air Force, Washington, D.C.
- 3 Cardiovascular Problems—William D. Stroud, 1011 Clinton Street, Philadelphia.
- 4 Chemotherapy—Chester S. Keefer, 65 East Newton Street, Boston.
- 5 Dermatology—
- 6 Dysenteries—Lieut. Col. Thomas T. Mackie, M.C.U.S. Army, 6817 Georgia Avenue N.W., Washington, D.C.
- 7 Epidemiology and Laboratory Medicine—Roy R. Kracke, 441 Clairmont Avenue, Decatur, Ga.
- 8 Gastrointestinal Diseases—Walter L. Palmer, 920 East 59th Street, Chicago.
- 9 General Internal Medicine—David P. Barr, 525 East 68th Street, New York.
- 10 General Surgery—Irvin Ahell, 321 West Broadway, Louisville, Ky.
- 11 Gynecology—Henry E. Meleney, 477 First Avenue, New York.
- 12 Neurology and Neurosurgery—Tracy J. Putnam, 710 West 168th Street, New York.
- 13 Nutrition—John B. Youmans, Vanderbilt University Hospital, Nashville, Tenn.
- 14 Orthopedic Surgery—George E. Bennett, 4 East Madison Street, Baltimore.
- 15 Physical Therapy—Frank H. Krusen, 102 Second Avenue S.W., Rochester, Minn.
- 16 Plastic and Maxillofacial Surgery—Robert H. Ivy, 1930 Chestnut Street, Philadelphia.
- 17 Psychiatry—Arthur H. Ruggles, 303 Blackstone Blvd., Providence, R.I.
- 18 Psychosomatic Medicine—John Romano, Cincinnati General Hospital, Cincinnati.
- 19 Radiology—Burl Kirklin, 102 Second Avenue S.W., Rochester, Minn.
- 20 Respiratory Diseases—Francis G. Blake, 789 Howard Avenue, New Haven, Conn.
- 21 Rheumatism and Arthritis—Ralph Pemberton, 2031 Locust Street, Philadelphia.
- 22 Shock, Burns and Plasma—Lieut. Col. Douglas B. Kendrick, Jr., M.C.U.S. Army, Medical Center, Washington, D.C.
- 23 Shock, Burns and Plasma—Commander Harold D. Newhouse, (M.C.) U.S.N., Naval Medical School, Bethesda, Md.
- 24 Thoracic Surgery—Leo Eloesser, 490 Post Street, San Francisco.
- 25 Traumatic Surgery of the Abdomen—Frederick A. Collier, 1313 East Ann Street, Ann Arbor, Mich.
- 26 Tuberculosis—Lieut. Col. Edward R. Long, M.C.U.S. Army, Army Service Forces, Office of the Surgeon General, War Department, Washington, D.C.
- 27 Urology—Herman L. Kretschmer, 122 South Michigan Avenue, Chicago.
- 28 Venereal Disease—Raymond A. Wondolch, U.S. Public Health Service, Washington, D.C.

U S PUBLIC HEALTH SERVICE FEATURED IN R K O "THIS IS AMERICA" FILM

Dr. Carl I. Rice, currently in charge of the Community Medical and Dental Section of the U S Public Health Service at Bethesda, Md., is featured in R K O's "Medicine On Guard," which tells the story of the typical wartime community faced by important health problems arising from the shortage of doctors. Dr. Rice works in close cooperation with the Procurement and Assignment Service of the War Manpower Commission and, when appealed to by the harassed local physician, arranges the relocation of a doctor from a less critical area. This latest "This Is America" two reel feature depicts the rising incidence of tuberculosis in a typical industrial community and again it is the U S Public Health Service that comes to the rescue. Under the direction of Dr. Herman I. Hilleboe, this movie is being checked through the use of the mobile photofluorographic units, which are set up in the factories themselves and take mass chest plates of the workers with a minimum of time loss and expense. The elaborate laboratories of the Bureau of Industrial Hygiene under the direction of Dr. James G. Townsend are shown determining the causes of occupational disabilities and thus keeping the industrial health of America at its usual high level. These aspects of the U S Public Health Service's home front battle against sickness and disease are illuminatingly and entertainingly filmed in "Medicine On Guard," which tells the story of a typical American community faced by these problems.

HEALTH OF THE NETHERLANDS UNDER HITLER

Constant friction between Dutch doctors and the Nazis, coupled with grave wartime shortages, are undermining the Dutch private and public health services, and the disease index of the occupied country has become alarming. Many persons have become so weak from wartime hardships that a slight ailment, even a common cold, may prove fatal. Medicines are either scarce or unobtainable. The harsh Nazi imposed working hours, the lack of fuel to warm homes and hospitals, and the wholesale conscription of Dutch nurses to aid the Germans on the fighting fronts have contributed to the complications in the Dutch medical-social sphere.

Lack of proper diet and overwork are breaking down the health of the Dutch people, a Dutch physician reported on his arrival in London in February. He declared that industrial fatigue had become so serious that work today required twice as many men as previously. The Dutch are living on food which gives them only about 1,500 calories a day, half the amount required from a normal diet. Reports reaching London on February 15 said that the Nazi authorities had decided to oust old people "whose recovery is doubtful" from hospitals to ease crowded conditions resulting from the increasing disease toll. Officials disclosed that more than 2,000 "serious cases" were waiting for hospital beds in Amsterdam alone. Diphtheria cases by December had reached 12,223, compared to 5,437 in 1941 and 1,273 in 1939. Dispatches in August of last year said that the tuberculosis mortality rate had increased between 39 and 44 per cent under German occupation and the death rate of newborn babies had become alarming.

Efforts of the Dutch Nazis to control the Netherlands Medical Society led to its dissolution early last year. All members received a letter urging them to resign and warning them of twelve objectives the Nazis hoped to attain. Ninety per cent of the members resigned and the board was dissolved. As an outcome of this dissolution and further German action, the Nazi Medical Front and the Netherlands Medical Chamber, headed respectively by the pro-Nazi physicians Keyer and C. C. A. Crom, virtually control all medical activities in the Netherlands today.

According to Dutch underground press reports received in London, Netherlands practitioners have refused membership in the Nazi Physicians Chamber on the ground that its governing principles are in conflict with their traditional ethics. The Nazi policy demands that doctors diminish the chances of life of the mentally afflicted or even kill them. The underground press stressed that Dutch doctors will continue to say no to all requests for collaboration with Nazi physicians.

The opposition has reached such scope that some Dutch doctors and Netherlanders in avoiding the compulsory conscription of labor for Germany, according to an article in *De Storm*, organ of the Dutch Nazi Storm Troops, which said that physicians were rejecting "healthy persons" as unfit and at the same time were giving certificates of health to "half dying persons" who must be hospitalized as soon as they reach the reich.

The war and occupation have dealt hard blows to what was one of the most advanced medical and public health organizations in the world. State subsidized hospitals with the most modern equipment were in operation throughout the country. The Central Institute for Brain Research at Amsterdam and the clinics at the Universities of Utrecht, Leyden, Amsterdam and Groningen had an international reputation which lured foreign specialists and students to the Netherlands. Today the doctors, nurses and medical students of the Netherlands are suffering from the same repression that throttles their compatriots. In the view of well informed observers the situation undoubtedly will grow worse steadily as long as the Nazis are in power.

PUBLIC HEALTH UNDER HITLER

According to NDZ of February 3, private health insurance in Germany covers nearly 10 million insured persons. In view of its growing importance, it is considered necessary that this branch of insurance should be controlled by specific regulations. The Committee for Insurance Law of the Academy for German Law has therefore submitted to the competent authorities regulations designed to fill this gap. A report says that health insurance should come under personal insurance and not under insurance against damage. Its main object is to compensate the insured for any expenditure on medical treatment. In addition, fixed benefits such as payments to dependents in case of death and maternity benefits are granted. The draft suggests that insurance companies should give full details of these benefits in their policies and tariffs.

Reichs-Gesundheitsblatt, Berlin, of January 20 gave the following figures for the incidence of infectious diseases in Germany during 1942, compared with 1941.

	1942	1941
Diphtheria	274,459	200,750
Scarlet fever	396,527	274,508
Tuberculosis (lung, throat)	125,794	116,302
Tuberculosis (skin)	1,818	1,896
Tuberculosis (other organs)	16,847	15,367
Meningitis cerebrospinalis	2,732	4,722
Encephalitis epidemica	419	652
Infantile paralysis	3,911	
Trachoma	8,514	8,161
Typhoid (typhus abdominalis)	16,015	7,630
Paratyphoid	5,916	4,855
Dysentery	15,070	10,278
Bacterial food poisoning	1,930	2,252
Ikterus infectiosus	103	90
Malaria	709	1,606

Nya Dagligt Allehanda, Stockholm, of February 4 reported that Norwegian hospitals are crowded out, partly because of the ruthless German requisitioning, partly because of increasing illness. It is reported from Oslo that skin diseases especially show an alarming increase. Syphilis, which was previously rare in Norway, is now not a phenomenon. Prostitution is widespread. Diphtheria epidemics are raging in several places, especially in Opland districts. Hospital conditions in Opland are beneath criticism. Most hospitals in the county have been requisitioned by the Germans, who force sick Norwegians to be treated in schools, meeting halls and the like under conditions which would have been rejected a hundred years ago.

Trots Allt! of February 12 quoted a circular by Himmler concerning the transport of prisoners of war saying that, since in spite of previous remonstrations prisoners are still arriving at their destination covered with lice, a thorough and careful delousing is ordered in order to avoid the danger of infection and spreading of spotted typhus. Himmler also prohibits the transport of seriously ill persons together with others, and sick prisoners must in future be medically examined. The paper comments that the regulations have not been issued out of humane consideration for the prisoners but in order to protect the Germans and because of the fear of infection.

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 10 30 p m Saturdays over Station WMAQ. Unless otherwise indicated, each program is summarized by Dr W W Bauer, Director, Bureau of Health Education.

The titles and guest speakers for the next four programs are as follows:

- May 8 'Drugs March to War'
Speaker, Dr Austin E Smith Secretary, Council on Pharmacy and Chemistry
- May 15 High Air

- May 22 'Flash Burns'
Speaker, Rear Admiral Ross T McIntire, M C, Surgeon General United States Navy
- May 29 Sick Call

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled 'Before the Doctor Comes' will be on the air every Thursday morning at 9 45 up to and including May 27. Mrs June Merrill will interview Dr W W Bauer, Director, Bureau of Health Education, or Dr Austin E Smith, Secretary, Council on Pharmacy and Chemistry, on common home health problems. The titles for the next four programs are:

- May 6 Foreign Bodies in the Nose Ears Throat or Eyes (Smith)
- May 13 Growing Pains' (Bauer)
- May 20 Nervous Habits (Bauer)
- May 27 Immunization' (Bauer)

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H R 1936 has passed the Senate, authorizing an appropriation of \$2,000,000 to expand the facilities for hospitalization of dependents of Navy and Marine Corps personnel and of certain persons outside the continental limits of the United States.

Bills Introduced—The President has submitted to Congress an estimate of appropriation for the Office of Defense Health and Welfare Services of the Office for Emergency Management for the fiscal year 1944, amounting to \$2,053,000. H Res 220, submitted by Representative Bonner, North Carolina, proposes to authorize the House Committee on Invalid Pensions to investigate the progress of the program of the Federal Board of Hospitalization to determine if such program is being carried forward efficiently and expeditiously so as to meet hospitalization problems that are likely to arise out of the present global war. H R 2548, introduced by Representative Patman, Texas, proposes to establish a Civilian Supply Administration with authority, among other things, to ascertain the quantities and types of goods and services, including but not limited to food, clothing, shelter, fuel, transportation and medical care, necessary to keep the civilian population healthy and functioning effectively. H R 2567, introduced by Representative Voorhis, California, proposes to establish a Temporary National Hospital Survey, to be composed of two members of the Senate, two members of the House, one representative each from the Department of War, the Department of the Navy, the United States Public Health Service and the Veterans Administration, and four additional members appointed by the President. This survey, it is contemplated, will make a full investigation with respect to the situation of hospitals and hospital beds now available or that can be made available for use by members of the military forces, a study of all buildings of any kind or character which are or may be adapted for hospitalization including hotels, spas, dude ranches, health resorts and national park establishments, and to study the hospital and health problems as a whole both as to war and as to the effect on civilian life of the various phases of the war.

STATE MEDICAL LEGISLATION

Connecticut

Bills Introduced—Substitute for S 259, to amend the law relating to the practice of natureopathy, proposes to authorize the granting of certificates without examination to persons who have been in active and continuous practice of natureopathy for three years immediately preceding the date of his application, provided that a person who applies for such certificate after his discharge from the armed forces of the United States must show that he had engaged in the practice of natureopathy for three years immediately preceding the date of his induction into such armed forces. S 804, to amend the chiropractic law, proposes to eliminate the requirement of professional study for a period of four years of thirty-six weeks each and to substitute therefor the requirement that such course consist of four years of eight months each, totaling not less than three thousand six hundred hours.

Florida

Bills Introduced—S 139 proposes to require any physician or other person who makes a diagnosis in or treats a case of, venereal disease to make a report thereof to the state board of health or to the local health officer and to make a further report in the event that such person ceases reporting to the physician prior to his having become cured or rendered non-infectious. S 141 proposes to require all persons rejected or deferred for military service who are infected with venereal disease to report to venereal disease clinics operated by the state board of health and take treatment from a private physician or at public expense for such venereal disease. H 37 proposes that each person applying for a marriage license must present a certificate signed by a qualified physician licensed to practice medicine and surgery in any state or United States territory certifying that the applicant is not infected with syphilis in a communicable stage. H 110 proposes that every person applying for a license to marry shall present a certificate from a duly licensed physician certifying that he or she is not infected with syphilis in a communicable stage. H 111 proposes that every physician attending a pregnant woman shall take or cause

to be taken, a sample of blood of such woman at the time of the first professional visit and submit such blood to an approved laboratory for a standard serologic test for syphilis. The person taking the sample must be a physician duly licensed to practice medicine. H 146 proposes that no person duly authorized to practice medicine and surgery shall be allowed to disclose any communication or information which he may have acquired in his professional capacity from any patient, except with the written consent of such patient or his legal representative. H 246 proposes that no person shall maintain or operate a maternity hospital without first obtaining a license therefor from the state board of health and defines a maternity hospital as a place which receives women for care or treatment during pregnancy or during delivery or within ten days after delivery.

Illinois

Bills Introduced—S 307 proposes the creation in the department of registration of an electrolysis committee for the purpose of examining persons desiring to practice electrolysis, defined as the removal of superfluous hair by means and use of an electrically charged needle. H 425 proposes to authorize the department of public health to establish, equip and maintain stations or distribution centers for breast milk for infants, to cooperate with hospitals in the collection, storage and distribution of such milk and to provide regulations necessary to safeguard the collection, storage and sale of such milk. H 437 proposes the enactment of an Illinois food, drug and cosmetic act.

Iowa

Bill Enacted—S 371 was approved, April 15. To amend S 82, concerning the income tax law, which was approved by the governor on March 11, 1943, S 371 provides that a taxpayer may deduct expenses paid during the taxable year, not compensated for by insurance or otherwise, for medical care of himself, his spouse or any dependent. The term "medical care" is defined to include amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body, and also treatment or nursing as prescribed by a well recognized church or religious denomination in any hospital or at home or in a sanatorium conducted and operated by such church or denomination.

Massachusetts

Bill Introduced—H 1519 proposes that hospital records shall be admissible as evidence in a court so far as they relate to the treatment and medical history of a case and authorizes a court to admit photographic or microphotographic copies thereof.

Michigan

Bills Enacted—H 277 has become Public Act No 204 of the Acts of 1943. It, among other things, prohibits druggists and pharmacists from selling barbituric acid and any of its derivatives, chloral hydrate or paraldehyde, except on prescription of a licensed physician, dentist or veterinarian. H 343 has become Public Act No 205 of the Acts of 1943. It prohibits a minor from purchasing, and a person from selling to a minor, any alcoholic beverage except pursuant to a prescription of a duly licensed physician.

Missouri

Bill Introduced—H 590, to amend the osteopathic practice act, proposes among other things to define osteopathy as the system, method, art or science of treating diseases, injuries or defects of the human body as taught and practiced by reputable colleges of osteopathy and surgery in the state, which practice shall include, without limiting the generality of the foregoing, operative surgery with instruments, obstetrics and the use of anesthetics, antiseptics, narcotics, biologics, antidotes, stimulants, scrums and vaccines.

Bill Enacted—H 45 was approved, April 13. Amending the law relating to marriage, it requires every person applying for a license to marry to furnish a report of a negative laboratory serologic test for syphilis and an affidavit signed by him or herself that he or she is free from such disease. If the laboratory test is positive, the applicant must present a certi-

cate from a physician licensed to practice in the state of Missouri certifying that the applicant is not infected with syphilis in a communicable stage.

Nebraska

Bill Introduced—Legislative Bill No 139, amending the law relating to the practice of medicine and surgery, was amended by proposing that any person now licensed to practice osteopathy in the state of Nebraska may, if application is made prior to July 1, 1948, take the regular examination given before the Board of Examiners in Medicine and Surgery, and, if successful, he shall receive a license to practice medicine and surgery in the state of Nebraska, provided, however, that any doctor of osteopathy now licensed and practicing in the state of Nebraska who is able to show satisfactory evidence of having taken and successfully passed the regular examination in medicine and surgery shall be issued a license hereunder on payment of the prescribed fee.

New Mexico

Bills Enacted—S 101 has become chapter 50 of the Laws of 1943. It requires the county school superintendent to see that all children in his county under 8 years of age are immunized against diphtheria. S 160 has become chapter 78 of the Laws of 1943. It provides that any person having a license to practice a profession in the state shall not be prejudiced by reason of having been drafted into the armed services but shall retain such license after release from such service. H 219 has become chapter 33 of the Laws of 1943. It amends the law relating to school employees by prohibiting the employment of teachers afflicted with syphilis and requiring all school employees to present annually a certificate from a licensed physician showing freedom from any transmissible disease, including tuberculosis and Wassermann tests.

Pennsylvania

Bills Introduced—S 526 proposes that a woman who is reasonably suspected of being afflicted with syphilis, gonorrhea or other venereal disease in a communicable stage and who is reasonably suspected of being, because of her habits, a carrier of such disease and a menace to the health of the community, may be ordered to an institution or hospital for medical treatment after an adequate hearing and on affidavit of at least one duly licensed physician verifying the existence of the venereal disease in a communicable stage. S 555 proposes the creation in the department of health of a bureau of health clinics with duties, among other things, to make surveys and investigations to determine the desirability or need of health clinics in certain areas, to prepare suitable facilities and appoint the necessary personnel for the establishment of such clinics and to assume charge of and operate any existing health clinic or merge the same with any existing or new project. H 235, proposing to authorize the state board of medical education and licensure to issue temporary certificates to physicians licensed in other states to authorize them to practice medicine and surgery in Pennsylvania for the duration of the present war and six months thereafter, was amended to provide that such temporary licenses must have scholastic qualifications equivalent to those required by the law of Pennsylvania.

Wisconsin

Bill Introduced—A Jt Res 53 proposes a resolution that the state board of health, state board of medical examiners, state board of dental examiners and the several professional societies be requested to ask all practicing physicians and dentists to ascertain, as far as possible, whether patients are now or are on any subsequent date veterans of the present war and, if so, to preserve case histories thereof for at least six years after the date of the last professional service rendered.

Bill Enacted—S 53 has become chapter 43 of the Laws of 1943. It exempts members of the armed forces from being required to maintain a license to practice any profession within the state and suspends such license during the active service of such person with the right to renew same within six months after his discharge from the armed forces.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

GEORGIA

Campaign Against Whooping Cough—The state department of public health, in cooperation with private practitioners, was to open up a campaign against whooping cough about April 15. The health department will absorb 80 per cent of the cost of the vaccine to be used, thereby making it available at a nominal price. Only infants above 5 months of age and those children below 3 years of age will be immunized.

Blood Donor Service Expands—The Atlanta Chapter of the American Red Cross is now housed in a new blood donor center at 291 Peachtree Street. The floor space has been divided so as to provide a registration room, a bleeding room, offices for the doctor in charge, the head nurse and the Volunteer Red Cross director, a canteen for the administrative staff where light refreshments will be served to blood donors after they have made their contributions, a recovery room, a telephone center with blackboards showing the daily schedule of appointments, and a laboratory with all equipment necessary for handling the blood donations. The blood will be sent from Atlanta to Indianapolis, where it will be turned into dried plasma to be shipped wherever needed.

Certification Form Omits Names of Parents—Under a recently enacted bill, the state department of public health is authorized to certify only the following items for the issuance of birth certificates: name of child, date of birth, place of birth, color and sex. The new certification form omits the names of parents and the information as to whether or not the child is legitimate. Certified copies of birth records containing complete information thereof shall be issued only by the state department of health or other officials authorized to issue certified copies of birth records on request of the person whose record of birth is registered, if of age; either parent of the person whose record of birth is registered; the legal representative of the person whose record of birth is registered; order of any court of record; any governmental agency, state or federal, provided such certificate shall be supplied without cost to the state.

ILLINOIS

State Expands Service to Mental Patients—The state department of public welfare announces that plans are being completed, in cooperation with universities and colleges, for the expansion and standardization of psychologic service to patients of the eleven state mental hospitals. The service, which will be under the supervision of the chief psychologist, to be appointed, will augment the psychiatric and social services which have become a part of the system of treatment and will remove the state hospitals further from being custodial institutions. Professional psychologists have already been placed at most of the hospitals and arrangements have been made with the University of Chicago, Northwestern University, MacMurray College, Jacksonville, and others to reinforce the staffs by assigning graduate students and interns in psychology. The program has been in effect at Elgin State Hospital, Elgin, with Phyllis Wittman in charge as psychologist, one assistant, two graduate students serving their internships as aides and a research fellow from the Social Science Service Council. The hospital has given training to twenty-eight graduate students in psychology.

Chicago

Personal—Dr. Gustavus M. Blech recently received a distinguished service citation from the American Legion Department of Illinois for services to nation, state and the community.

Course in Motility of the Eyes—The semiannual course in motility of the eyes from a neurologic point of view will be presented at the Children's Memorial Hospital by Dr. George P. Gubior, May 9-14. The class is limited to those interested in motor difficulties of the eyes.

LOUISIANA

State Medical Meeting—The sixty-fourth annual meeting of the Louisiana State Medical Society at the Heidelberg Hotel, Baton Rouge, May 3, will consist of a business meeting of the house of delegates and an evening session devoted to the presidential address by Dr. Emmett Lee Irwin, New Orleans, a memorial address for deceased members, and the annual oration by Gov. Sam Houston Jones, Baton Rouge. The woman's auxiliary to the society will also meet at the Heidelberg Hotel.

Training in Medical Librarianship—The residency in medical library work sponsored by the Orleans Parish Medical Society Library, New Orleans, will be open on August 15. Appointment will be made on July 1. Requisite qualifications for appointment include college and library school training and an evidence of fitness for this type of work, by personality and aptitude. The appointment carries a nominal salary and is for a term of one year. The work is done in the library of the Orleans Parish Medical Society and its cooperating unit, the Rudolph Matas Medical Library of Tulane University School of Medicine, comprising a collection of approximately sixty-five thousand volumes. The course is personally directed by the librarian in charge of the two libraries and proposes to cover a study of medical library administration used in these libraries and a comparison with varying methods used elsewhere. Any one wishing further information should address the librarian, Orleans Parish Medical Society Library, 1430 Tulane Avenue, New Orleans.

MASSACHUSETTS

New Professor of Bacteriology at Tufts—Dr. Ralph E. Wheeler, assistant professor of preventive medicine and public health, Vanderbilt University School of Medicine, Nashville, Tenn., has been named to a new professorship of bacteriology at Tufts College Medical School, Boston, effective April 1. Another chair of bacteriology is held by Basil G. Bibby, D.M.D., Boston, dean of the dental school. Dr. Wheeler graduated at Harvard Medical School, Boston, in 1926, receiving the degree of doctor of public health at Johns Hopkins University, Baltimore, in 1932. Dr. Wheeler has served as consultant and later surgeon in the U. S. Public Health Service and as research associate of the Milbank Memorial Fund of New York.

MICHIGAN

Changes in Faculty at Wayne University—Dr. Clement A. Smith, formerly of Boston, has been appointed professor of pediatrics at Wayne University College of Medicine, Detroit, effective May 1. He succeeds Dr. James L. Wilson, Detroit, who has accepted a position on the faculty of New York University College of Medicine. Dr. William E. Abbott, Cleveland, has been appointed instructor in surgery at Wayne and Dr. John W. Hirshfeld has been promoted to assistant professor of surgery.

Graduate Program—The spring "Michigan Program for Graduates in Medicine" opened in April in eight lower peninsula cities—Ann Arbor, Bay City, Flint, Grand Rapids, Jackson, Kalamazoo, Mount Clemens and Traverse City. In the upper peninsula, meetings are planned to begin in Sault Ste. Marie, May 24, Marquette, May 25, Houghton, May 26, Ironwood, May 27 and Powers, May 28. The program is conducted semiannually by the Michigan State Medical Society in cooperation with Wayne University College of Medicine, Detroit, the University of Michigan Medical School, Ann Arbor, and the Michigan Department of Health, Lansing.

MINNESOTA

State Medical Meeting—The ninetieth annual session of the Minnesota State Medical Association will be held at the Hotel Radisson, Minneapolis, May 17-19, under the presidency of Dr. Stephen H. Baxter, Minneapolis. A symposium on fractures will open the meeting Monday and each day round table luncheons will be held to cover a wide range of medical topics. Among the speakers on the program will be:

Dr. Ralph K. Ghormley, Rochester, Tendon Injury
Dr. Frank C. Neff, Kansas City, Mo., Practical Applications of a Routine Blood Count in the Newborn with Special Reference to the Oil Tetracycline
Dr. James M. Hayes, Minneapolis, Fatigue in Repair of Heart
Dr. Everett D. Kiefer, Boston, Pericardial
Dr. John M. Wrough, Rochester, N. Y., Heart
Capt. Erik G. Hakala, Jr. (MC), U.S.N., Control of Trauma
Dr. Herman O. McPheters, Minneapolis, Skin Grafting
Albert E. Russell, Chicago, U.S. Public Health Service, Silica

Other topics to be discussed on the program will be care of the aged, abnormal uterine bleeding, cardiovascular disease, myasthenia gravis, newer therapeutics in surgery and child health in wartime. Dr. Ralph S. Brimer, Bryn Mawr, Pa., will deliver the annual Russell D. Carman Memorial Lecture, Monday, on "Roentgen Diagnosis of Diseases of Infants and Children." Three special societies are sponsoring visiting speakers for the meeting: the Minnesota Radiological Society, Dr. Brimer, the Northern Minnesota Medical Association, Hon. Walter H. Judd, congressman from the Fifth District, and the Northwestern Pediatrics Society, Dr. Neff.

MISSISSIPPI

State Medical Meeting—The seventy-sixth annual session of the Mississippi State Medical Association will be held at the Heidelberg Hotel, Jackson, May 12-13, under the presidency of Dr. H. Lowry Rush, Meridian, whose address will be entitled "Today's Challenge to Medicine." Among the speakers will be:

Dr. Claude C. Pierce, New York, Conception Control—A Public Health Responsibility

Dr. Julius W. Davenport Jr., New Orleans, Human Blood Plasma—A Review of Its Preparation and Clinical Indications for Its Use

Dr. John J. Shea, Memphis, Tenn., Lung Problems of the Ear, Nose and Throat

Dr. William B. Clark, New Orleans, Glaucoma

Dr. Edgar Burns, New Orleans, Recent Advances in Treatment of Carcinoma of the Prostate

Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health, American Medical Association, Industrial Medicine and the General Practitioner

The Ewing Fox Howard Oration will be delivered Tuesday evening at a public session by Dr. Charles C. Bass, New Orleans, on "Prevention of the Loss of Teeth."

NEBRASKA

Outbreak of Scarlet Fever—Two hundred and eighty-two women students at the University of Nebraska, Lincoln, were quarantined, April 5, in a women's residence hall after a medical checkup revealed 32 cases of scarlet fever, newspapers reported. It was stated that an isolation ward had been set up in the dormitory and the 32 patients placed there.

NEW HAMPSHIRE

State Medical Meeting—The one hundred and fifty-second annual meeting of the New Hampshire Medical Society will be held at the Hotel Carpenter, Manchester, May 11, under the presidency of Dr. Timothy F. Rock, Nashua. Among the speakers will be:

Dr. John P. Bowler, Hanover, Carcinoma of the Prostate and Its Endocrine Relationships

Dr. Oliver Cope, Boston, The Treatment of Burns

Dr. Roger I. Lee, Boston, Geriatrics: The Medical Care of the Elderly

Dr. Andre William Reggio, regional medical officer, First Civilian Defense Region, Boston, Civilian Medical Defense and Its Adaptation to Peacetime Civil Life

Dr. George V. S. Smith, Brookline, Mass., Female Sex Hormone Therapy

The Woman's Auxiliary to the New Hampshire Medical Society will hold its eighteenth annual meeting at the same time. Speakers will include Tshyi Hsieh, Boston, on "China's Vital Role in World Democracy."

NEW YORK

Dr. Whipple Awarded Medal—The Civic Medal, awarded annually by the Rochester Museum Association, will be presented on May 13 to Dr. George H. Whipple, dean of the University of Rochester School of Medicine and Dentistry. In 1934 Dr. Whipple was co-winner with Drs. George R. Minot and William P. Murphy of Boston of the Nobel Prize in Medicine.

Forum on Increase of Manpower—An open forum of the Buffalo District Committee for Industrial Health was devoted on April 16 to the theme "Increase Manpower Through Industrial Health." A panel discussion was held with Dr. Herbert H. Bauckus, Buffalo, acting as chairman and Dr. Clarence D. Selby, Detroit, leading the discussion on "Industrial Health in the Nation at War."

Child Care Group Formed—The Buffalo Victory and Child Care Association, Inc., has been organized to share with the local government one third the cost of expensive facilities for the caring for children of women workers, the New York Times reported April 6. Under a recent state law, the residual cost is to be shared equally by the state and the mothers. Children up to 14 years of age will be eligible for care under

the program, which, it is planned, will be in operation by July 1. Harold B. Ehrlich, assemblyman, has been named executive secretary of the new group which represents the war industries of the region. A movement is now under way to extend the plan to cover all war and allied industries in Erie and Niagara counties.

New York City

Epidemic of Infantile Diarrhea—Up to April 11 ten deaths had occurred in an epidemic of infantile diarrhea in the Staten Island Hospital at Tompkinsville, according to the New York Times. The cause of the outbreak had not been determined. The maternity and pediatric departments of the hospital have been closed and all new cases are being cared for at St. Vincent's Hospital at West New Brighton.

Suspend License of Dr. Cowles—The medical license of Dr. Edward Spencer Cowles was suspended on April 16 for one year by the state board of regents, which found him guilty of "fraud and deceit" in his conduct of his Body and Mind Foundation, the New York Times reported. The action of the board was unanimous, and the suspension will become effective with the service of a formal order. The Body and Mind Clinic at 139 East 69th Street was closed in April 1942. The state began proceedings to close the clinic on the grounds of unlawful practice of medicine, charging Dr. Cowles with unethical conduct in permitting two employees, Robert Rebold, a chemist, and Mrs. Eveline Dolin Schulman, a psychologist, to practice medicine without licenses. The prosecution charged, it was stated, that the clinic did a \$500,000 a year business for treating patients in mass meetings for mental disorders. The clinic was put out of business by the court of special sessions on June 16, the Times stated. Rebold was convicted but received a suspended sentence. Mrs. Schulman was acquitted. Dr. Cowles went on trial before the subcommittee of the state medical grievance committee on May 22, the hearings being conducted at long intervals. Dr. Cowles, aged 63, graduated at the University College of Medicine, Richmond, Va., in 1907. The first Body and Soul Medical and Mental Foundation, as it was originally called, was established by him in July 1923 in the Episcopal Church of St. Mark's-In-The-Bowwerie. It continued there until 1932, when it was ousted, after a quarrel with the vestry, the Times stated. The clinic moved to 142 Second Avenue and after two years to a converted garage at 139 East 69th Street, the name being changed to Body and Mind Foundation, Inc. (THE JOURNAL, May 9, 1942, p. 197 and July 4, 1942, p. 819).

Committee to Study Medicine and the Changing Order—The New York Academy of Medicine has organized a committee to study medicine and the changing order with Dr. Malcolm Goodridge as chairman. The objectives of the committee are defined as follows:

To be informed on the nature, quality and direction of the economic and social changes that are taking place now and that are clearly forecast for the immediate future; to define in particular how these changes are likely to affect medicine in its various aspects; to determine how the best elements in the science of medicine and its services to the public may be preserved and embodied in whatever changed social order may ultimately develop.

The committee plans to survey the changes that are currently taking place in economic and social organization likely to take place during the next decade. It will solicit opinions from a wide variety of groups including sociologists, economists, representatives of organized labor, industrialists, bankers and politicians, as well as the cooperation of persons actually connected with medicine in the capacities of deans of medical schools, teachers of medicine, hospital authorities, hospital clinicians, public health workers, those interested in graduate education, physicians in industrial medicine, medical social workers and workers in voluntary health organizations. The committee seeks to devote itself primarily to the study of how, within the changing social order, the best qualities in medical service, in medical education and in medical research can be preserved and developed. It is expected that the study will continue until such time as sufficient evidence has been accumulated to make possible a considered report. In addition to Dr. Goodridge, other members of the committee include Drs. Arthur F. Chace, James Alexander Miller, Alan Gregg, George Baehr, Washington, D. C., Harry Aranow, I. Ogden Woodruff, Paul Reznikoff, Henry W. Cave, Tracy J. Putnam, Wilson G. Smilie, Jean A. Curran, Brooklyn, Herbert B. Wilcox, Howard R. Craig, Edward Tolstoi, Eugene H. Pool, Robert E. Pound and Iago Galdston, secretary.

NORTH CAROLINA

State Medical Meeting—The ninetieth annual session of the Medical Society of the State of North Carolina and the twenty-first annual meeting of the woman's auxiliary to the society will be held at the Hotel Sir Walter, Raleigh, May 10-12. Speakers will include

Lieut. Col. Charles W. Mayo, M. C. Army of the United States. One Stage Combined Abdominoperineal Resection for Malignancy of the Lower Colon, Rectosigmoid and Rectum.
Dr. William Banks Anderson, Durham. Unilateral Exophthalmos as a Diagnostic Problem.
Dr. LeRoy M. Polvogt, Baltimore. Recent Advances in Chemotherapy as Applied to Otolaryngology.
Capt. Waltham Walters, M. C. U. S. Naval Reserve. Treatment of War Casualties.
Capt. Carl T. Javert, M. C. Army of the United States. A Combined Isometric and Stereoscopic Technique for Radiographic Study of the Obstetrical Patient.
Drs. William H. Sprunt and James A. Harrill, Winston-Salem. Diagnosis and Treatment of Cardiospasm.
Dr. Grace G. Jones, Charlotte. Retroperitoneal Position of the Ascending Colon.
Dr. Richard S. Lyman, Durham. Some Principles of Diagnosing Malingering and Hysteria.
Major Philip W. Brown, M. C. Army of the United States. Amebiasis.
Dr. Walter R. Berryhill, Chapel Hill. Atypical Pneumonia of Unknown Etiology.

There will also be a report of the committee on award of Moore County Medal for the best paper read in 1942 session and presentation of the medal to Dr. Edwin P. Alvea, Durham, for his paper on "Castration for Carcinoma of the Prostate Gland."

SOUTH CAROLINA

Journal Club Formed—The Medical Journal Club was recently organized at the Veterans Administration Facility, Columbia, for the purpose of perusing current literature in the fields of internal medicine and surgery. Membership is open to staff physicians of the veterans hospital as well as to physicians in Columbia. Officers are Drs. Solomon L. Zimmerman, president; Manuel D. Zane, secretary; and P. Mertz, treasurer.

TEXAS

New Hospital Association Officers—Miss Eva M. Wallace, R.N., superintendent, All Saints Episcopal Hospital, Fort Worth, was chosen president-elect of the Texas Hospital Association at its meeting in Fort Worth, February 18-19, and Mr. A. C. Seawell, superintendent, City and County Hospital, Fort Worth, was installed as president. The association decided to hold its next meeting in Dallas, Feb. 23-24, 1944. The recent meeting of the association was a war conference.

WISCONSIN

The William Snow Miller Lecture—Dr. Marius N. Smith-Petersen, clinical professor of orthopedic surgery, Harvard Medical School, Boston, gave the sixteenth annual William Snow Miller Lecture at the University of Wisconsin Medical School, Madison, April 15, under the auspices of Phi Beta Phi. His subject was "Arthroplasty."

Personal—Dr. Harold M. Coon, Madison, medical superintendent of the State of Wisconsin General Hospital, was recently elected president of the Wisconsin Hospital Association at its meeting in Milwaukee. Walter E. Sullivan, Ph.D., professor of anatomy and chairman of the department, University of Wisconsin Medical School, Madison, is serving for six months as visiting professor of anatomy at Washington University School of Medicine, St. Louis. Dr. Marshall W. Meyer, Ashland, former director of sanitary district number 9 in that city, has been named director of district number 6. He succeeds Dr. Allan A. Filek, now director of the division of local health service and tuberculosis control of the state board of health, Madison.

Guide Published for Special Diets in Rationing Program—The *Wisconsin Medical Journal* for April carried a special supplement entitled "Extra Ration Points for Special Diets." Prepared in cooperation with the Dane County War Price and Rationing Board by a special committee of the Dane County Medical Society, the supplement is a guide for the physician and rationing boards in the procedure to be followed in providing extra ration points. Members of the committee are Dr. Elmer L. Sevringhaus, chairman; Jack S. Supernaw, John E. Gonce, Jr., James P. Dean, Nels A. Hill, Lester McGarry, and the following dietitians: Esther Bast, Methodist Hospital; Jennette Mikeljohn, Madison General Hospital; Ruth Dickie, State of Wisconsin General Hospital; and Elizabeth Hilgers, St. Mary's Hospital, all of Madison.

GENERAL

Theobald Smith Award—The Theobald Smith Award of \$1,000 and a bronze medal of the American Association for the Advancement of Science, established by Eli Lilly and Company in 1935, has been awarded to Dr. Sidney C. Madden, assistant professor of pathology, University of Rochester School of Medicine and Dentistry, New York, for his investigations on "Plasma Proteins."

American Psychiatric Association—"War Psychiatry" will be the theme of the annual meeting of the American Psychiatric Association at the Hotel Statler, Detroit, May 10-13. The program will include presentations concerned with the psychiatric evaluation of men to be inducted into the armed forces, the care of psychiatric casualties of the war and the treatment of men discharged from the army for psychiatric disability. Attention will also be given to the relationship of psychiatry and industrial hygiene.

Standards for the Protection of Workers in Gas and Electric Welding—The Division of Labor Standards of the U. S. Department of Labor, Washington, D. C., has reprinted in pamphlet form the manual called "Standards for the Protection of Workers in Gas and Electric Welding," prepared by the State of New Jersey Department of Labor. These standards are for the practical guidance of superintendents and foremen, putting special emphasis on health hazards due to fumes, dusts and glare as well as accident risks from fire, explosion and shock. Copies of the pamphlet may be obtained by writing to the Division of Labor Standards, U. S. Department of Labor, Washington, D. C.

Florence Seibert Awarded Achievement Prize—Florence B. Seibert, Ph.D., associate professor of the Henry Phipps Institute, Philadelphia, was presented April 13, with the first \$2,500 achievement award of the American Association of University Women. The fund for the award was raised by the Northwest Central Section of the association. Mrs. H. K. Painter, Minneapolis, regional vice president of the association for the northwest central section, participated in the ceremonies and Kathryn McHale, Ph.D., Washington, D. C., general director of the association, made the presentation in the Philadelphia branch headquarters of the association. The citation accompanying the award pointed out that it was designed to help Dr. Seibert with her research in tuberculosis.

Meeting of Neurologists—The American Neurological Association will hold its sixty-ninth annual meeting at the Waldorf-Astoria, New York, May 6-7. The presidential address will be delivered by Dr. Ernest Sachs, St. Louis, on "The Contributions of War to Medicine." Among the speakers will be

Dr. Geoffrey Jefferson, Manchester, England. Neurologic Interpretation of Acute Head Injuries.
Dr. Foster Kennedy, New York. Functional Nervous Disorders as Reported in the Present War.
Dr. John Young, Nuffield Institute, England. Process of Regeneration of Nerve and Muscle Following Immediate and Delayed Suture.
Dr. Joseph C. Yaskin, Philadelphia, and Major Melvin W. Thorne, M. C. U. S. Army. The Effects on the Cerebral Cortex of Altitude Chamber Anoxia.
Dr. Kenneth G. McKenzie, Toronto, Canada. One Aspect of the Post-Traumatic Syndrome in Craniocerebral Injuries.
Dr. Samuel B. Hadden, Philadelphia. Group Psychotherapy.

Psychoanalytic Association—The forty-fifth annual meeting of the American Psychoanalytic Association will be held at the Hotel Statler, Detroit, May 9-12, under the presidency of Dr. Karl A. Menninger, Topeka, Kan. The speakers will include

Dr. Ives Hendrick, Boston. Instinct and the Ego During Infancy.
Dr. Carl M. Herold, New York. Pleasure Principle and Drive Therapy in Reference to Psychophysiology.
Dr. Sander L. Orland, New York. Psychoanalytic Investigation of Reaction to the War Crisis of Candidates for Induction.
Dr. Rene A. Spitz, New York. Prophylaxis versus Treatment in Treatment in Traumatic Neuroses.
Dr. Gregory Zilboorg, New York. The Fear of Death in War and Peace at Home and in the Field.

The program also includes a symposium on Present Trends in Psychoanalytic Theory and Practice with Dr. Lewis B. Hill, Baltimore, as the moderator.

Judicial Commission on Bacteriologic Nomenclature—A judicial commission on bacteriologic nomenclature has been selected following recommendations approved at the third international congress of microbiology in New York in September 1939. The selection of the committee was of necessity made by ballot, the choice finally being completed in November 1942. A communication from Robert S. Breed, Ph.D., head of the division of bacteriology, New York State Agricultural Experiment Station, Geneva, N. Y., asks that con-

creation be given to the belated appointment of this committee in order that some plan for taking tentative action on questions of nomenclature may be developed by those members of the commission who can be reached under war conditions. Robert E. Buchanan, Ph.D., Ames, Iowa, has been asked to act as chairman pro tem of the judicial commission, as there is no possibility of securing an election under the rules as adopted. Dr. Breed with Dr. Ralph J. St. John-Brooks, London, are the joint permanent secretaries of the International Committee on Bacteriological Nomenclature. The members of the committee, as reported by Dr. Breed, are Dr. Buchanan, A. I. Khayyer, the Netherlands, F. G. D. Murray, Montreal, Canada, S. Orla Jensen, Denmark, James Howard Brown, Ph.D., Baltimore, A. R. Prevot, France, James Ramsbottom, Great Britain, I. Hjort, Norway, A. Iwasz, France, R. Renaux, Belgium, Alfredo Sordelli, Buenos Aires, Argentina and C. Stipp, Germany.

Drug Manufacturers Association—The annual convention of the American Drug Manufacturers Association will be held at the Palmer House, Chicago, May 2-4. Among the speakers will be:

- Dr. Elmer I. Scrimgeour, Madison, Wis., Commercial Production of Hormone and Vitamin Extracts
- Milton A. Veldt, Bethesda, Md., Senior Surgeon, U. S. Public Health Service, The Place of Biologists in Warfare
- John K. Timbs, Legal Staff, Office of Price Administration, The Operation of the OPA in Relation to the Drug Industry, Including an Explanation of the Automatic Regulation Establishing Maximum Prices for Drugs
- Donald S. Whitney, Attorney, Norwich Pharmaceutical Company, Norwich, N. Y., A Review of Important Cases Affecting the Drug Industry
- Franklin Bliss Snyder, Ill. D., Evanston, Ill., Education, Research and the War
- Lawrence A. Appleby, executive director, War Manpower Commission, Washington, D. C., Full Mobilization and Utilization of Manpower in Time of War
- Dr. Austin E. Smith, Chicago, Secretary, Council on Pharmacy and Chemistry, American Medical Association, Research and Therapeutics
- Joseph D. Coppock, price executive, Office of Price Administration (subject not announced)

Dr. Alexander W. Lescolmer, Grosse Point, Mich., will be toastmaster at the dinner May 3 with Anton J. Carlson, Ph.D., Chicago, on "How We May Improve Our Respective Performance for a Better National Health" and the Hon. C. Wavland Brooks, Chicago, United States Senator. A luncheon session on May 4 will be addressed by Dr. Morris Fishbein, Editor, *THE JOURNAL*, with John S. Zimser, Philadelphia, presiding. One feature will be a symposium on military medicine conducted by Col. Clifford V. Morgan, M. C., U. S. Army. The symposium will be divided into a consideration of the plans and operations, aviation medicine, supply service and the treatment of burns. Among the speakers will be Lieut. Col. Arthur B. Welsh, Col. Walter S. Jensen and Col. Morgan, all of the army medical corps, and Capt. Erik G. Erikson (MC) USN. Other military speakers on the program will be Brig. Gen. Charles C. Hillman, Brig. Gen. James S. Simmons, Brig. Gen. George F. Lull, Col. Charles F. Shook Sr., Col. Martin E. Griffin, all of the army medical corps, and Capt. Carlton L. Andrus (MC) USN. They will take part in the discussions of the various subjects.

Deaths in Other Countries

William Albert Hoffman, Sc.D., assistant professor of parasitology at the Columbia School of Tropical Medicine, San Juan, P. R., was found dead in his office, April 4. Dr. Hoffman had been with the school of tropical medicine since 1926, devoting his researches chiefly to medical entomology.

Government Services

Annual Report of United States Public Health Service

The Office of War Information has decided that the annual reports of the Surgeon General of the U. S. Public Health Service will be discontinued for the duration of the war.

Annual Report of Veterans Administration

The total hospital load of the Veterans Administration was 56,346 for the fiscal year ended June 30, 1942, as compared with 58,417 on June 30, 1941, according to the annual report of the Administrator of Veterans' Affairs. The neuropsychiatric load increased 154 and the tuberculosis 257, while the

general load decreased 2,482. At the close of the year 76.82 per cent of the United States veterans under hospitalization were receiving treatment for disabilities not of service origin as compared with 78.53 per cent for the previous comparable period. Of the total patient load 56,073 were United States veterans, classified by service as follows: World War I, 49,140; World War II, 832; Spanish-American War, 2,951; Civil War, 18; all other wars, expeditions and occupations, 55; and Regular Establishment, 3,077. There were 12,999 United States veterans under treatment for diseases or injuries determined to be of service origin, of whom 10,201 had service in World War I, 743 in World War II, 22 in the Spanish-American War, 2,032 in the Regular Establishment during peacetime, and 1 in other wars, occupations or expeditions. In addition to United States veterans there were under treatment 31 veterans of countries allied with the United States in the World War, 18 employees of the Civilian Conservation Corps and Work Projects Administration and 224 miscellaneous beneficiaries. Of the patients in hospitals at the close of this year, 87.7 per cent were under treatment for tuberculosis, 61.59 per cent for neuropsychiatric diseases and 29.64 per cent for general medical and surgical conditions. Of the 56,073 United States veterans under treatment at the end of the year, 52,999 were in facilities controlled by the veterans administration, 2,080 in other government hospitals and 994 in state or civil institutions.

An analysis of the types of hospital admissions of veterans shows that 62,082, or 34.6 per cent of the total, were first admissions, 109,232, or 60.9 per cent, readmissions, and 7,960, or 4.5 per cent, admissions by transfer from other facilities. During the year 9,658 admissions were authorized for the observation and treatment of pulmonary tuberculosis, 10,200 for psychotic or mental diseases, 14,101 for other neurologic disorders and 145,315 for general medical and surgical conditions. During the year 242,157 patients were under hospitalization, of whom 239,001 were United States veterans. Of the latter group 182,928 were discharged after an average of 78.7 inpatient days. Deaths in hospitals totaled 12,977, or 7.09 per cent of the discharges as compared with 12,891 in 1941. Of the total deaths 9,354 occurred in patients under treatment for general conditions, 1,919 for pulmonary tuberculosis and 1,704 for neuropsychiatric diseases. Of the 9,354 deaths among general patients, about 28 per cent were caused by diseases of the circulatory system, about 25 per cent by malignant tumors and about 9 per cent by diseases of the digestive system. On June 30, 1942 the veterans' administration was operating hospital facilities at ninety-two locations in forty-five states and the District of Columbia. These facilities had a capacity of 62,453 beds, an increase of 604 over the number available on July 1, 1941. A new hospital was opened at Marion, Ill., and additional beds were provided at Jefferson Barracks, Mo., Los Angeles, Newington, Conn., Perry Point, Md., Tuscaloosa, Ala., and Whipple, Ariz. The administration was also using 1,599 beds in other government hospitals. There were 18,371 beds set aside for domiciliary care in facilities under the veterans administration facilities as compared with 18,747 on June 30, 1941, a decrease of 376, due primarily to loss by fire at Dayton, Ohio. At the close of the recent fiscal year work was in progress on thirteen projects to provide 1,256 beds.

The net operating expenses for all hospital and domiciliary facilities controlled by the veterans administration totaled \$64,891,086, of which \$59,054,871 was for hospital and \$5,836,214 for domiciliary facilities. This amount does not include expenditures for new construction, improvements, construction alterations, maintenance and operation of personnel quarters, nonexpendable equipment or those for the diagnostic centers at San Francisco and Hines, Ill. Throughout the year there was a daily average of 54,636 patients of all types under treatment and a daily average of 14,371 beneficiaries receiving domiciliary care, as compared with 54,582 and 16,696 respectively during the fiscal year 1941. The per diem cost of operation for hospital facilities used principally for the treatment of tuberculosis was \$4.37, for those used exclusively for the treatment of neuropsychiatric diseases \$2.02, and for those used largely for the treatment of general medical and surgical conditions \$4.24. Collectively the per diem cost of operation for hospital facilities of all types was \$2.96. The per diem cost of operation for domiciliary facilities for this year was \$1.11.

Three new physical therapy clinics were opened at Perry Point, Md., Tuscaloosa, Ala., and Marion, Ill. One in the Los Angeles facility was closed temporarily because of the partial evacuation program instituted because of its critical location. An artificial fever therapy clinic was established at the Northport, Long Island, N. Y., facility and will be used as a center for training other physicians and nurses in the administration of artificial fever.

Preparations for the Relief of Europe After the War

The appalling misery of Europe under German occupation, including the starvation of children, has been described in previous letters. Although we are engaged in our maximum war effort we are preparing relief measures, so that they can be applied immediately on liberation of the occupied countries without waiting for an armistice. The need for this is shown in a lecture to the British Red Cross Society by Dr Melville Mackenzie, principal medical officer of the Ministry of Health. He pointed out that in the three years following the last war more died from famine and preventable disease than had been killed in the war itself and that their deaths were largely the result of administrative chaos in relief. Already malnutrition, with its resulting diseases particularly tuberculosis, is widespread. It is estimated that at the present moment 200 million persons in Europe are urgently in need of more food. Typhus fever is now epidemic in most of eastern and much of central Europe as well as in Spain and North Africa. Malaria also is increasing.

Food of course, is the primary need, and then come medical supplies. The control of epidemic diseases—typhus, malaria, dysentery and tuberculosis—is urgent. The medical hospital and health services have to be reestablished. In all the occupied countries there is a shortage of doctors, nurses and midwives. There is also a shortage of potential doctors, for many universities have been closed by the Germans and most of those who would be medical students are serving in the armies. The reorganization of the faculties of medicine of the universities of Europe will be a pressing need.

In September 1941 an allied conference was held in London on postwar requirements. A committee representing fourteen governments was set up to enable the allied governments to collaborate in supplying food and other necessities immediately on liberation of the occupied countries. An allied postwar requirements bureau was established to assist the various governments in preparing estimates of relief requirements. The staff of this bureau is provided by the British government. The work is carried on mainly by technical advisory committees, of which there is a medical one containing representatives of the British, American and allied governments. The work of this medical advisory committee covers the whole of Europe. In order to obtain the best technical advice, expert subcommittees have been set up on such subjects as drug and hospital requirements including those for surgery, radiology, dentistry and bacteriology, tuberculosis, maternity and child welfare, malaria, typhus, typhoid, dysentery, cholera and diphtheria.

Another Munificent Gift from Lord Nuffield to Medicine

The name Nuffield will rank for benefactions with Carnegie, Rhodes and Rockefeller. The latest gift of this automobile magnate eclipses his previous numerous donations and like many of them helps medicine. Lord Nuffield has stated his intention of founding forthwith a charitable trust to be known as the Nuffield Foundation for which he will hand over to trustees his shareholdings in the Nuffield Organization to the value of \$50,000,000 as a capital fund. Among the managing trustees are two members of the medical profession—Prof. Sir John B. Stopford (anatomist) and Miss Janet Vaughan (pathologist). The objects which the trustees will endeavor to assist are medical research and teaching organization and

development of medical and health services, scientific research and teaching in the interests of trade and industry, social studies, and the care and comfort of aged persons. The managing trustees are enjoined to consult the appropriate ministers or departments of state in connection with any matter of major importance in which they may become interested, but they are not to be in any way bound by the views expressed. Lord Nuffield points out that his donation comes from resources built up by private enterprise, in the importance of which he is a firm believer. This declaration is needful at a time when people are looking to the state to do so much for them.

Articles of Clothing and Bedding Not Important in the Dissemination of Scabies

In a memorandum issued by the Ministry of Health it is stated that recent investigations have shown that while articles of clothing and bedding may play some part in the spread of scabies, their importance as a means of dissemination has been much overestimated and that with standard methods of treatment (benzyl benzoate emulsion or sulfur ointment) routine disinfection of clothing is unnecessary, as the layer of medication which covers the body after treatment is usually sufficient to kill all mites on the clothing. Moreover, in view of the small reinfestation rate when disinfection has been abandoned, it is simpler to repeat treatment rather than expend an amount of manpower and material required for routine disinfection in all cases. Emphasis should rather be laid on the follow-up treatment of the family and other close contacts of the original case. On occasion disinfection may be justified, as for instance when there is a high incidence of scabies among people living in overcrowded conditions and compelled to use communal bedding and clothing.

Blood Transfusion in the Desert

The distribution of blood to the army fighting in the Middle East has been a most difficult problem. In the Libyan battle of 1941 blood was sent by air to those advanced depots of medical stores that had oil burning refrigerators. From these it was collected by field transfusion units and taken to casualty clearing stations or other places. Advanced depots in battle areas held stocks of dextrose-saline solution, serum, dried plasma and apparatus for replacement. In the recent battle of El Alamein a more elaborate system was adopted which is described in the *Army Medical Bulletin*. A field transfusion unit was located at the advanced air transport center, to which blood was brought by airplane from the base. This unit collected if necessary stored and then forwarded the blood by ambulance airplane if available, or by refrigerator truck, to an augmented field transfusion unit stationed in the medical concentration area where a number of casualty clearing stations were situated. From this unit supplies were issued (1) to the casualty clearing stations and other transfusion units and (2) to an advanced blood bank consisting of a refrigerator truck with personnel. The latter supplied casualty clearing stations in the vicinity and units in the more inaccessible southern section of the line.

For transporting the blood boxes are made from salvaged tin and wood by a carpenter and a tinmith employed at a base transfusion unit. They are tin lined so that small boxes or bottles of ice can be packed round the bottles. It was feared at first that blood in transit across the desert would hemolyse through jolting and splashing in its bottle. But this was found to happen very little. When possible blood is not used more than three weeks after it has been taken, but blood five weeks old which showed only slight hemolysis has been transfused with success. Units with the British expeditionary force in France used blood after seven weeks storage. But five weeks is a long time to preserve blood in a hot country.

and speaks well for the refrigeration. Between Oct. 16 and Nov. 5, 1942 nearly 11,000 bottles or ampules containing fluids for intravenous use were sent forward, including 3,220 bottles of fresh blood obtained by the base transfusion unit from troops in the base area.

TEL AVIV, PALESTINE

Feb. 14, 1943

(From Our Regular Correspondent)

Epidemic of Lymphocytic Choriomeningitis

Following sporadic cases of benign meningitis in various parts of Palestine, Dr. Falk of the General Federation of Jewish Labor in Palestine reported a number of cases in Hadera in May 1941. By June the outbreak assumed the character of an epidemic, reaching its peak in July, with a rapid decline in August and a drop to only a few isolated cases in the following three months. Sixty-six cases were carefully examined, but the incidence was undoubtedly much greater. Only a few infants were affected, the majority of victims being between the ages of 4 and 7. A few adults contracted the disease. Examination showed that the epidemic attacked certain blocks of houses, but it was comparatively rare for several members of the same family to contract the disease, which began suddenly, without prodromal symptoms, with high fever and intense headache, vomiting and cramps. The temperature curve was almost constant high for two or three days, followed by a one to three day afebrile interval and then a slight rise in the curve. In a number of cases a tumor of the spleen developed. Leukocytes were between 6,000 and 25,000. The differential count was not characteristic. The usual symptoms of meningitis were not always distinctly observable, and often the typical spinal fluid finding and subjective symptoms were absent. The nerves of the brain were unaffected, however, 2 cases of encephalitis occurred, apparently connected with the meningitis. In half the cases the cell rate in the fluid was up to 100. In several cases a large number of segmented cells in the fluid were found. The fluid was usually clear. A fine fibrin clot was also found. The pressure was usually raised, and the qualitative albumin reaction was nearly always positive, while the quantitative reaction was 12 to 66 mg per hundred cubic centimeters, the average being 36. The sodium chloride rate fluctuated between 519 and 661 mg per hundred cubic centimeters and the sugar in the fluid from 51 to 75 per cent. The mastic curve only occasionally showed slight rises up to 221,000. It was impossible to prove the presence of bacterial organisms or virus in the blood and fluid. We can only determine, therefore, the nearest clinical relationship but not the actual identity of the disease with benign lymphocytic choriomeningitis. According to the observations of Dickens, Baird and Ribers, the distinguishing feature is probably the fact that considerable polynucleose is found in the fluid instead of lymphocytose, and that the number of cells in the fluid is often not particularly high.

The disease was in almost all cases benign, usually without complications. In a few cases the knee jerk reflex was absent for some time. Except for lumbar puncture and symptomatic therapy, no other treatment was necessary.

The First Case of Madura Foot in Palestine

Madura foot was formerly considered a disease peculiar to tropical countries, however, it occurs, though rarely, in temperate and subtropical climates.

Madura foot, or more correctly, mycetoma pedis, is the name applied to pathologic processes appearing mainly in the area of the leg but sometimes also in other parts of the body, such as the hand or the abdomen, the symptoms of which are swelling, the formation of fistulas and wrinkling of the epidermis. The processes are conditioned by the growth of various fungi, which are also called mycetoma grains, bodies

of different sizes, shapes and colors, made up mainly of mycelium threads and sometimes also of chlamydospores. The fungi are found in the infected epidermis or in the liquid excrescence. The grains are yellow, white, red or black and are formed in the process of the struggle of the fungus with the powers of resistance of the mycelium.

This disease was first heard of in India (the island of Madura is situated opposite to Java). Cases were later reported from other countries. Apart from India the disease is known in Brazil, Argentina, Africa and most of the Mediterranean countries. More than half of the cases in Europe occurred in Italy and Greece. The first case in Italy was reported by Bassini in 1888. Catsaras in Greece described some cases. One case came to light in Turkey. Several reports of the disease were received from Tunisia and Algeria. Cleveland and Williamson reported cases from Cyprus, and recently 1 case was heard of in Yugoslavia. One case has been reported from Portugal. Until the present instance the disease was unknown in Palestine.

Dr. Dostrowski, director of the Department of Dermatology at the Hadassah-University Hospital in Jerusalem, and his assistant Dr. Sagher give the following report of the first case of Madura foot, which they encountered in an agricultural laborer aged 32, a native of Aden, who has been resident in Palestine five years. His health has been sound, and his family origins are healthy. Six months ago he experienced a swelling the size of a lentil on the sole of his left foot. Ten days later the infected part softened and pus was released. Five days later there appeared on the sole of the foot a second nodule 10 cm away from the first. In a month almost the entire sole became covered with such nodules, accompanied with swelling. In the last few months before the patient entered the hospital no further nodules appeared. Throughout the whole period pus was present within the nodules, and slight pain was experienced when walking. The urine and excrement, as well as the blood count, were normal. Chemically the blood was normal. The Wassermann and Kahn reactions were negative. The gastric juice contained an excessive quantity of acid. The microscopic histologic analysis proved the presence of Mycetozoa fungi.

The question as to whether this case was contracted in Palestine or imported from abroad is difficult to decide. It is possible that the source of the disease in this case is Palestine, because it has been found in other countries of the Middle East and is known to be common in the Arabic countries. The occurrence of the disease in Yemen is described by Patton and Clemoy. It is therefore possible that our patient brought Madura foot with him in a latent form from Aden.

Marriages

GEORGE D. BROYLES JR., Palestine, Texas, to Miss Laura Elizabeth Carlson of Chicago, February 11.

WAYNE H. CRUM to Miss Anna A. Thornburg, both of St. Petersburg, Fla., in Tampa in March.

HERSCHEL COCHRAN SUDBUTH, Caddo, Okla., to Miss Olivia Jewell Sims at Tupelo, Miss., in March.

ARTHUR KLEIN, Woodbridge, N. J., to Miss Beatrice Dean Temko in Richmond, Va., February 28.

ABRAM BERRY, Columbia, S. C., to Miss Bernice Frances Coleman of Charleston in March.

CARL B. SPUTH JR. to Miss Ruth Agnes Means, both of Indianapolis, February 10.

DAVID CLEMENTS FRICK to Miss Lois Louise Scott, both of Toledo, Ohio, April 11.

KENNETH H. SCHNEPP to Miss Lois Catron, both of Springfield, Ill., March 31.

NATHAN ZIMMERMAN to Miss Minette Kositchek, both of Chicago, April 9.

Deaths

Thomas Jefferson Harris, Tucson, Ariz., University of Pennsylvania Department of Medicine, Philadelphia, 1889, member of the Medical Society of the State of New York, specialist certified by the American Board of Otolaryngology, an honorary member and formerly member of the board of directors, member of the American Academy of Ophthalmology and Otolaryngology, fellow, secretary from 1907 to 1916 and president in 1917, American Laryngological, Rhinological and Otolological Society, fellow, past president and for many years secretary of the American Otolological Society, past president and secretary of the New York Laryngological Society and the New York Otolological Society, past president and secretary of the New York Physicians Mutual Aid Association, member of the permanent commission of the International Otolaryngological Congress, fellow of the American College of Surgeons, formerly professor, diseases of the nose and throat, New York Post-Graduate Medical School, Columbia University, New York, served as consulting surgeon in the throat department of the New York Post-Graduate Medical School and Hospital, New York, and on the staff of the Manhattan Eye, Ear and Throat Hospital, New York, from 1922 to 1940 president of the Jennie Clarkson Home for Children, Valhalla, N. Y. served as lieutenant colonel in the medical corps of the U. S. Army during World War I, in charge of the department of otolaryngology at the General Hospital, number 14 at Fort Oglethorpe, Ga., and director of the school of laryngology at Camp Greenleaf, Ga. aged 77, died, March 14, in the Veterans Administration Facility, Northport, N. Y.

Alfred Mitchell Jr. @ Prouts Neck, Maine Medical School of Maine, Portland, 1898, member of the New England Surgical Society and the American Urological Association, fellow of the American College of Surgeons, formerly instructor in genitourinary diseases at his alma mater in 1903 was appointed adjutant surgeon of the Maine General Hospital, Portland and later chief of the urologic service serving until 1937 on the consulting staffs of the Queen's Hospital, Children's Hospital, and the former St. Barnabas Hospital in Portland, the Bath City Hospital, Bath, the Webber Hospital, Biddeford, St. Mary's General Hospital, Lewiston, and the Goodall Hospital, Sanford, served during World War I aged 70, died February 8 in Georgetown, Mass., of heart disease.

William Howes Bishop @ New York, Hahnemann Medical College and Hospital of Philadelphia, 1889, at one time professor of surgery at the New York Medical College and Flower Hospital during World War I served as a major lieutenant colonel and colonel in the medical corps of the U. S. Army, awarded the Distinguished Service Medal and made a Chevalier of the Legion of Honor of France for his exceptionally meritorious and conspicuous service with the base hospital at Orleans, France, fellow of the American College of Surgeons, consulting surgeon to the Flower and Fifth Avenue Hospitals and the White Plains (N. Y.) Hospital, medical director for the Todd Shipyards Corporation, aged 75, died, March 9, of coronary thrombosis.

William Mercer Sprigg @ Washington, D. C., Columbian University Medical Department, Washington, 1885, past president and vice president of the Medical Society of the District of Columbia, formerly associate professor of obstetrics at the Georgetown University School of Medicine, served on the staff of the Georgetown University Hospital, attending obstetrician at the Columbia Hospital for Women and Living-In Asylum from 1912 to 1937, from 1884 to 1887, superintendent and resident physician and for over thirty years on the staff of the Garfield Memorial Hospital, a member of the board of directors and on the staff of the Medical Center and Doctors Hospital where he died March 6 of cerebral hemorrhage, aged 78.

Irving Eugene Charlesworth @ Inola, Calif., Medical-Chirurgical College of Philadelphia, 1906, past president, vice president and secretary of the Napa County Medical Society, past president of the Cumberland County (N. I.) Medical Society, served as a major in the medical corps of the U. S.

Army during World War I, formerly associated with the U. S. Public Health Service Reserve, past president and director of the International Rotary in Napa, member of the chamber of commerce and the council on national defense, medical director and superintendent of the Napa State Hospital, aged 66, died, February 28, in the University of California Hospital, San Francisco, of carcinoma.

Herbert Eldridge Milliken, Cape Elizabeth, Maine, Medical School of Maine, Portland, 1901, formerly instructor in medicine at his alma mater, for many years a member of the attending staff of the Maine General Hospital, Portland, fellow of the American College of Surgeons, served during World War I, lieutenant colonel, medical reserve corps, U. S. Army, not on active duty, at one time consultant in internal medicine for the U. S. Public Health Service, while a resident of Waterville served as city physician, secretary of the Waterville Clinical Society and for one term president of the Kennebec County Medical Association, aged 63, died, February 9, in Portland of heart disease.

Marlin C. Crane, Wittenberg, Wis., Milwaukee Medical College, 1902, member of the State Medical Society of Wisconsin, served during World War I, for his work at Yokohama harbor during the Japanese earthquake in September 1923, when he was in the medical service of a Netherland steamship company, received a medal from the Netherland mercantile marine, a silver medal from Queen Wilhelmina and a loving cup from the persons he assisted, at one time on the staff of the U. S. Public Health Service Hospital, Palo Alto, Calif., aged 66, died February 17, in the Shawano (Wis.) Municipal Hospital of chronic myocarditis and coronary occlusion.

Frederick George Dyas @ Hinsdale, Ill., Northwestern University Medical School, Chicago, 1904, professor of surgery, emeritus at the University of Illinois College of Medicine, specialist certified by the American Board of Surgery, member and past president of the Western Surgical Association, member of the American Association for the Surgery of Trauma, fellow of the American College of Surgeons, major medical corps U. S. Army, 1918-1919, attending surgeon to the Cook County Hospital, Chicago, Brown (Ill.) Hospital and the Hinsdale Sanitarium and Hospital, aged 69, died March 4, of heart disease.

Paul Stanislaus Wagner @ Major, U. S. Army, retired, Redwood City, Calif., Rush Medical College, Chicago, 1911, graduated from the School for Flight Surgeons in 1920, the Medical Field Service School in 1922 and the U. S. Army Medical School in 1923, commissioned a first

lieutenant in the medical corps of the U. S. Army in 1918, became a captain in 1919, retired with rank of major for disability in line of duty in 1929, at one time assistant clinical professor of military medicine at his alma mater, aged 58, died February 13, in the U. S. Marine Hospital, San Francisco, of coronary thrombosis.

James Byron Ashley, Detroit, University of Michigan Medical School, Ann Arbor, 1941, served an internship at the Harper Hospital, first lieutenant in the medical corps, Army of the United States, aged 25, was killed in action at Guadalcanal, January 13.

Andrew A. Baxter, Brandenburg, Ky., Hospital College of Medicine, Louisville, 1890, member of the Kentucky State Medical Association, aged 76, died February 14, in the SS. Mary and Elizabeth Hospital, Louisville, of coronary occlusion.

William Franklin Bell, Plain Dealing, La., Memphis (Tenn.) Hospital Medical College, 1901, member of the Louisiana State Medical Society, aged 67, died February 17, in a hospital at Shreveport of cerebral thrombosis.

Hiram Franklin Bigony, Kirtlandville, Ohio, Medical College of Virginia, Richmond, 1905, member of the Licking County Board of Health and Harrison township board of education, aged 68, died February 13, in the White Cross Hospital, Columbus, of angina pectoris.

L. August H. Bishop, Dover, Del., University of Pennsylvania Department of Medicine, Philadelphia, 1875, in active practice in Dover since 1877, member and in 1912 president

KILLED IN ACTION

LIEUT. JAMES BYRON ASHLEY, M. C.,
A. U. S., 1917-1943

of the Delaware State Medical Society, a charter member and past president of the Kent County Medical Society, surgeon for the Pennsylvania Railroad Company at Dover for fifty-two years, aged 90, on the staff of the Kent General Hospital, where he died, March 13, of heart disease.

Addison A. Blassingame of Denison, Texas, University of Texas School of Medicine Galveston, 1897, on the staff of the Denison City Hospital and formerly president of the board, formerly member of the staff of the Missouri, Kansas and Texas Railroad Employees Hospital, local surgeon for the Kansas, Oklahoma and Gult Railway and the Southern Pacific Railroad, aged 68, died March 1, in the Baylor University Hospital, Dallas, of endocarditis and septicemia following a transurethral prostatectomy.

Harl H. Bronson, Kansas City, Mo., Marion Sims College of Medicine St. Louis, 1896, aged 67, died, February 3.

John Creighton Buchanan, Winnsboro, S. C., Medical College of the State of South Carolina Charleston, 1887, chairman of the board of public works of Winnsboro, aged 80, died suddenly, February 28, of coronary thrombosis.

George Washington Buckner, Evansville Ind., Indiana Eclectic Medical College, Indianapolis, 1890, formerly U. S. minister to Liberia, on the staff of the Welborn-Walker Hospital, aged 87, died, February 17, of myocarditis.

Neill Henry Buie, Lavette, Miss., Medical Department of Tulane University of Louisiana, New Orleans, 1890, aged 76, died February 26, of carcinoma of the lungs with metastases.

Robert Ira Bull of Newark, N. J., Long Island College Hospital, Brooklyn, 1904, aged 62, died February 17, in the Presbyterian Hospital.

Elham Baxter Burns of Ecorse, Miss., Vanderbilt University School of Medicine, Nashville, Tenn., 1915, aged 59, died, February 12, of pneumonia and rheumatic fever.

Charles Augustus Caldwell, Blitheville Ark. (licensed in Arkansas in 1903), member of the Arkansas Medical Society, aged 65, died, February 8.

Hawes Campbell, Enfield, Va., University College of Medicine, Richmond, 1898, member of the Medical Society of Virginia, health officer of King William County, aged 69, died, February 23, of a self-inflicted gunshot wound.

Lloyd Logan Carr, Baltimore, Jefferson Medical College of Philadelphia, 1876, member of the Medical Society of the State of New York, aged 89, died, February 21, of heart disease.

William Henry Carter, Wichita, Kan., Kansas City (Mo.) Medical College, 1904, member of the Kansas Medical Society, formerly on the staff of the Wichita Hospital, aged 65, died, February 12, of angina pectoris.

John Bunyon Chapman, White Bluff, Tenn. (licensed in Tennessee in 1910), aged 70, died, February 11, in Nashville.

Howard Paxton Collings of Hot Springs National Park, Ark., Bellevue Hospital Medical College, New York, 1891, member of the House of Delegates of the American Medical Association in 1905, past president of the Garland County Medical Society, fellow of the American College of Surgeons, aged 78, on the staffs of the Ozark Sanatorium and St. Joseph's Infirmary, where he died, March 5, of coronary occlusion.

John F. Culler, Lucas, Ohio, Jefferson Medical College of Philadelphia, 1886, aged 82, died, February 24, of cerebral hemorrhage.

Chester C. Dodge, Chicago, Chicago Homeopathic Medical College, 1887, a retired school principal, aged 91, died, March 13, of arteriosclerotic decompensated heart disease.

George William Fuller, Long Beach, Calif., Hospital College of Medicine, Louisville, Ky., 1901, aged 68, died, February 21, of coronary thrombosis.

Jacob Arthur Fulton, Astoria, Ore., Northwestern Medical College, St. Joseph, Mo., 1881, Bellevue Hospital Medical College, New York, 1884, member of the Oregon State Medical Society, fellow of the American College of Surgeons, on the staff of the Columbia Hospital, past president of the staff and

was instrumental in the establishment of a nurses' training school at St. Mary's Hospital, where he died, February 21, of carcinoma of the liver, aged 85.

Pattison Fulton, Cincinnati, Hahnemann Medical College and Hospital of Philadelphia, 1940, resident assistant in the department of pathology at the Good Samaritan Hospital, commissioned a lieutenant, junior grade, medical corps of the U. S. Naval Reserve, attached to the Marine Corps, posthumously awarded the Silver Star Medal for conspicuous gallantry and intrepidity, aged 27, died, December 3, at Guadalcanal, Solomon Islands, of shrapnel wounds received in action two days earlier.

Bert Edward Greer, Dallas, Texas, Washington University School of Medicine, St. Louis, 1900, member of the State Medical Association of Texas, aged 66, on the staffs of St. Paul's Hospital and the Methodist Hospital, where he died, February 25, of uremia and acute nephritis.

Frederick Casper Harms, Saugerties, N. Y., University and Bellevue Hospital Medical College, New York, 1909, veteran of the Spanish-American War, aged 63, died, February 15, of coronary occlusion and arteriosclerosis.

Henri Joseph Ap John, Jacumba, Calif., Willamette University Medical Department, Salem, Ore., 1892, at one time associated with the Indian Service, aged 76, died, February 26, of arteriosclerotic heart disease.

Howard Hill Markel of San Francisco, University of California Medical Department, San Francisco, 1911, assistant clinical professor of orthopedic surgery at his alma mater, president-elect of the Western Orthopedic Association, member of the American Academy of Orthopaedic Surgeons, member of the board of the California Society for Crippled Children, for many years consultant to the Southern Pacific General Hospital, on the staffs of St. Francis Hospital and the University of California Hospital, aged 63, died, February 13, of coronary disease.

Harriet L. Post, Duluth, Minn., Woman's Medical College of the New York Infirmary for Women and Children, New York, 1883, aged 83, died, February 24, of cerebral arteriosclerosis and rheumatic heart disease.

John Calhoun Rice, Braden, Tenn., Memphis Hospital Medical College, 1902, member of the Fayette County School Board, aged 64, died, February 13, in the Baptist Memorial Hospital, Memphis, of coronary occlusion.

Samuel Henry Smith of Cincinnati, Medical College of Ohio, Cincinnati, 1907, aged 68, member of the staff of the Good Samaritan Hospital, where he died, February 6, of chronic obstructive pulmonary emphysema, bronchopneumonia and myocardial insufficiency.

Joseph Townsend Travers of New York, Long Island College Hospital, Brooklyn, 1908, member of the Radiological Society of North America, Inc., on the staffs of the Bellevue, Manhattan State and Jewish Memorial hospitals, aged 55, died, February 20.

J. R. Whittington, Gloster, Miss., Louisville (Ky.) Medical College, 1873, aged 93, died, February 28.

DIED WHILE IN MILITARY SERVICE

Martin Edward Harlan, Onawa, Iowa, State University of Iowa College of Medicine, Iowa City, 1938, member of the Iowa State Medical Society, on the staff of the Onawa Hospital, aged 31, lieutenant, junior grade, M. C., U. S. Naval Reserve, was accidentally drowned in Australia, February 20.

George William Smith, Niagara Falls, N. Y., Dalhousie University Faculty of Medicine, Halifax, N. S., Canada, 1925, member of the Medical Society of the State of New York, captain in the medical corps of the United States Army Air Corps, aged 42, died, March 22, in Salt Lake City.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts A Mere Allergic Condition Not Compensable—The workman, a man of about 41 years of age was employed from 1935 to August 1940 in the gasoline and petroleum products bulk station of the defendant corporation unloading gasoline from tank cars and loading gasoline into trucks. Sometime after entering into his employment he developed a dermatitis or skin eruption which did not result in any disability. In the summer of 1939 an eruption developed on his hands, arms and face which was diagnosed by a dermatologist as an allergic dermatitis due to contact with gasoline and for which he was treated at intervals for about two months. On April 27, 1940 he again developed an eruption on his hands and was again treated until June 22, 1940, when the eruption was pronounced as cured. He continued at his regular work until Aug 31 1940, when the employment was terminated by the employer because the workman "was allergic to gasoline poison. He instituted proceedings under the workmen's occupational disease act of Indiana for compensation, "alleging that in the performance of his duties [of his employment] he was exposed to an occupational disease and that he is afflicted therefrom with 'gasoline poisoning-dermatitis-due to gasoline poisoning'." The industrial board found that the workman contracted an occupational disease by reason of his employment, that he was totally disabled from that disease on Aug 31 1940, the date his employment was terminated by the employer and that he was totally disabled from that date until the hearing before the board, some four months later. An award of compensation was made accordingly in his favor, and the employer appealed to the appellate court of Indiana.

The employer contended that there was no evidence to sustain the finding of the industrial board that the workman became totally disabled on Aug 31, 1940 on account of an occupational disease and that there was no evidence to support the finding that the disability was continuous from that date until about four months later. The workmen's occupational disease act of Indiana, said the appellate court, provides that

The term disability means the event of becoming disabled from earning full wages at the work in which the employee was engaged when last exposed to the hazards of the occupational disease by the employer from whom he claims compensation or equal wages in other suitable employment and disability means the state of being so incapacitated. (Section 16503 Baldwin's Ind Statute Supp 1937 to 1934)

Applying the facts in this case, said the court to the section just quoted we conclude that the finding and award of the industrial board was erroneous. The workman was not disabled on the 31st day of August 1940. The evidence is absolutely to the contrary. Nor is there any evidence that the workman was disabled subsequent to that time. In fact, the workman's attending physician testified that the cause of the dermatitis was contact with gasoline and that functionally the workman has a normal body and that he can engage in any other activity that any other human being can provided he has the training and equipment, and that he is not disabled from following any other occupation except that which exposes him to gasoline and that he always will have that allergy. It is true continued the court that the workman possibly still has the allergy and that if he comes in contact with gasoline there is a probability of his being afflicted with the dermatitis again but on Aug 31 1940 he was not so afflicted. When his employment was terminated on that date he suffered no disability that carried any loss of time or wages or that would entitle him to be designated as disabled under the act. While it may be said that the dermatitis from which the workman suffered was contracted by coming

in contact with gasoline while working for the employer, the workman was not so afflicted on the date of the termination of his employment nor has he been since that date. It is possible that the allergy still exists, but a fair interpretation of the act leads us to the conclusion that a more allergic condition from which some affliction might develop was not contemplated in the act.

The award in favor of the workman was accordingly reversed.—*Smolan Refining Co v West, H N L (2d) 175 (Ind, 1912).*

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fifteenth Annual Meeting, held in Chicago, Nov. 6 and 7, 1942

The President, DR ARLIF R. BARNES, Mayo Clinic, Rochester, Minn., Presiding

(Continued from page 1413, Volume 121)

Icterus Accompanying Pneumonia in the Negro

DRS EDWARD L. TURNER, MICHAEL J. BENT, GUERNEY D. HOLLOWAY and JOHN R. CUFF, Nashville, Tenn. Basal physiologic factors that might indicate a racial predisposition to jaundice were ruled out by studies of 98 normal Negro subjects by checking erythrocyte and leukocyte counts, hemoglobin, bleeding and coagulation time and corpuscular fragility. Using rabbits and dogs, it was found that icterus could not produce accompanying pneumonia unless there was accompanying liver damage. Liver damage was produced by means of carbon tetrachloride, by high fat diets and finally by nutritionally inadequate diets identical with those consumed by some of the Negro patients before they developed pneumonia. When pneumonia was artificially induced in animals whose livers had been damaged either through the use of carbon tetrachloride or through nutritionally deficient diets, van den Bergh reactions became positive, while they remained negative in animals fed normal diets and then given pneumonia. In a final series of 7 dogs, 3 were kept on diets that were entirely adequate and 4 were placed on a diet of overcooked greens, fat meat, corn meal and sorghum, similar to the diets used by many Negro families in the lower economic brackets. When pneumonia was produced in these 7 animals three to seven weeks following the initiation of the dietary regimen, positive van den Bergh reactions were obtained in all the animals on the deficient diets while the van den Bergh test remained negative in the controls.

It is our belief that the high incidence of icterus observed in the 74 Negro patients with lobar pneumonia was due primarily to nutritional deficiencies which rendered the liver more vulnerable to the effects of pneumococcal infection.

DISCUSSION

DR M. A. BLANKENHORN, Cincinnati. I should like to ask whether there is any relation between the fatality rate and the icterus. Were the fatality rates higher in Negroes than in white persons in that particular epidemic? In the Cincinnati General Hospital Negro patients show no higher fatality rates than white patients, nor do they show higher incidence of nutritional disease.

DR EDWARD L. TURNER, Nashville, Tenn. In a group of 74 patients the mortality rate was in the neighborhood of 25 per cent. It was lower than the average hospital mortality rate. Since we have used sulfonamide drugs and have been pushing the idea of vitamin intake a little more in our patients we have seen a definite lowering of the incidence of jaundice in this group. It is rather interesting that Osler said some years ago that jaundice occurs in pneumonia in various degrees in different years. In some years it is more, in other years it is less. Our patients were not necessarily underweight but they certainly had a severe vitamin deficiency. We see quite a bit of subclinical pellagra. We see many cases of beriberi and there is a great deal of what might be called subclinical vitamin deficiency in the Negro when on this kind of a diet.

Prevention of Tooth Decay

DR JULIAN D. BOYD, Iowa City. This report is offered as evidence that tooth decay is preventable through measures directed not toward the tooth but toward the advancement of the level of nutrition. It is based on the prolonged study of 55 teen-aged children, each of whom was observed repeatedly both as to medical and as to dental status over periods of years. In all but 3 of the subjects caries made no advance for long periods of time, in most of them no significant degree of advance occurred throughout observation. With the exception of the 3 mentioned, all were living under a prescribed regimen of diet and their medical condition (diabetes mellitus) made it likely that the prescribed regimen of diet was followed with fair constancy. Prior to the establishment of the dietary regimen these children had caries experience in degree similar to what would be predicted for an average child population.

Subsequent to the establishment of the diet the incidence of caries progression was inversely proportional to the constancy of diet observance. Twenty children had no advance of caries for an average interval of five and one-half years, 35 had no caries for three years or longer, 44 had none for periods exceeding two years. For the whole group the average rate of advance was less than a fifth of what would be predicted for the general child population. The 3 children who failed to show arrest of caries were unable because of socioeconomic reasons to follow the prescribed regimen for any significant period, their rate of caries advance equaled or surpassed the predicted "normal" rate. In other subjects, when caries was observed to advance, the period of advance usually could be identified with an interval of abandonment or of relaxation of the prescribed regimen. During such periods the rate of advance corresponded with that observed in the average child without diet supervision.

The degree of freedom from caries at 13 years of age was directly proportional to the duration of diet control prior to that time, all those whose diet control was instituted prior to the age of 6 years were entirely free from caries at the age of 13. The annual caries increment subsequent to 13 years likewise was closely dependent on the prior duration of diet control but was lessened notably even in those who had assumed diet control in their teens.

Correlations were made between the fluorine content of domestic water supplies of each child and his extent and increment rate of caries. No significant correlation was demonstrated.

This report is not concerned with the characteristic of the diabetic diet which led to the reduction of caries. The point at issue is that caries progression is preventable and that this is accomplished through measures not directed toward the teeth but toward the maintenance of excellent health and nutrition in the subject as a whole.

DISCUSSION

DR JOHN TUCKER, Cleveland. This paper gives further evidence of the importance of a well balanced diet in the maintenance of sound tooth structure. I believe however, that once more the dentists are becoming interested in the relationship of bacterial growth to tooth decay. Many of us recall the frequent admonitions of our parents to avoid eating candy and sweets, especially at night. With this thought in mind, I should like to ask Dr Boyd whether he restricted carbohydrates in the children's diet, especially at the evening meal or at bedtime.

DR JULIAN D BOYD, Iowa City. The intake of sweets automatically is lessened if a child eats all the foods his body needs for proper functioning. Dr Icie Macy (Nutrition and Chemical Growth in Childhood, Springfield, Ill, Charles C Thomas, 1942, vol 1, p 84) recently presented data to indicate that the desire for sweets is lessened if an optimum diet is ingested. I feel that bacteria play no more than a secondary role in the causation of caries and that if sugar promotes tooth decay it does so through replacement of foods needed for the body's normal functioning rather than by any regional effect. I tell parents that if children eat all the dietary ingredients prescribed I will not prohibit the use of sweets in reasonable amounts. I prescribe daily 1 quart of milk, one or two eggs, a liberal serving of meat, fish, chicken or liver, two liberal servings of vegetables, a similar amount of fruit and a teaspoon of cod liver oil. Such a basic diet will furnish only about 1,200 calories. The remainder of the energy quota may be supplied through any type of food. I believe that, if the child eats and assimilates the foregoing foodstuffs daily, caries will be negligible in its extent.

Histaminic Cephalgia Resulting in Production of Acute Duodenal Ulcer

DR BAYARD T HORTON, Rochester, Minn. The outstanding complaint of histaminic cephalgia is of acute attacks of excruciating pain which involves the eye, temple, neck and often the face. It usually occurs at night, will awaken the patient out of a sound sleep and cause him to jump out of bed and pace the floor in a vain attempt to get relief. These attacks usually last from a half to one hour. The pain is associated with the following signs, all of which appear on the affected side: profuse watering and congestion of the eye,

rhinorrhea or stuffiness of the nose, increased surface temperature, and often swelling of the temporal vessels. These headaches have been refractive to other types of treatment but are eradicated within a period of two to three weeks by "desensitization" to histamine.

The direct relationship between acute duodenal ulcer with crater and histaminic cephalgia has been studied in detail in 10 cases during the past year. The formation of the ulcer in each instance has been secondary to the attacks of histaminic cephalgia. During such attacks the gastric acids rise to an abnormally high level just as they would if the patient had received approximately 0.35 mg of histamine subcutaneously. These subjects have all been hypersensitive to histamine—so much so that even 0.01 mg of histamine has been sufficient in many instances to precipitate a rise in gastric acidity which is the same as that which occurs among normal subjects following the subcutaneous administration of 0.35 mg of histamine base. Treatment of the histaminic cephalgia by means of histamine desensitization without other treatment for the duodenal ulcer itself not only has eradicated the attacks of histaminic cephalgia but has permitted the duodenal ulcer to heal promptly within a period of two weeks.

DISCUSSION

DR ELMER L SEVINGHAUS, Madison, Wis. I have seen 2 patients who almost met Dr Horton's criteria. I can appreciate the difficulty from overtreatment when the dosage of histamine is too large. I should like to inquire whether unilateral lacrimation is part of the syndrome. Just recently Dr St John and I examined a patient who had typical bilateral headache produced by the hypodermic administration of histamine. I wonder whether Dr Horton feels that there are other varieties of histamine cephalgia.

DR G E WAKERLIN, Chicago. Several groups of investigators have reported that lesions in the upper brain stem give rise to gastric and duodenal ulcers in dogs which can be prevented by bilateral vagotomy. It is possible that the genesis of the ulcers in these patients may in part be due to impulses passing down from the cerebral cortex and the diencephalic region via the vagi to the stomach and duodenum.

DR HEINRICH NECHELES, Chicago. I wonder whether Dr Horton is still using histaminase in the treatment of this syndrome.

DR BAYARD T HORTON, Rochester, Minn. In practically every instance the attacks of histaminic cephalgia have been unilateral. In about 3 instances out of perhaps 200 subjects I have observed bilateral lacrimation. This represents the exception, not the rule. I am not familiar with lesions in the brain stem producing peptic ulcers which might in some way be comparable to the series of patients I have just presented. It must be kept in mind that these subjects with histaminic cephalgia have no clinical evidence of lesions in the brain stem and neurologically they are objectively negative. Histaminic cephalgia is such a clearcut clinical syndrome that one no longer needs to defend it. I have been able to eradicate attacks of histaminic cephalgia in a few subjects by the giving of histaminase in large amounts by mouth. That histaminase can be useful as a therapeutic agent when taken by mouth, in my experience at least, is definitely established. As to just how it acts I do not know.

Treatment of Essential Hypertension with Large Doses of Ascorbic Acid

DRS N S DAVIS III and EDWARD FALK POSER, Chicago. Ascorbic acid may be a constituent of the enzymes required for the normal oxidation, dehydrogenation or deamination of amino acids by renal cells. By such action it may prevent the formation of pressor amines and renin in the ischemic kidney or it may inhibit the reaction between renin and hypertensionase to form hypertensin (angiotensin). By its action in the adrenal glands ascorbic acid may inhibit the formation of hypertensioninogen. The administration of ascorbic acid in doses of 1 Gm daily to a small number of patients with essential hypertension has caused objective or subjective clinical improvement or both in almost all of those to whom it has been administered. It seems to offer a logical physiologic approach to the treatment of essential hypertensive cardiovascular renal disease which is worthy of further trial.

DISCUSSION

Dr G E WAKERLIN, Chicago It is known that ascorbic acid functions as a hydrogen acceptor in plant cells. This may also be true for animal cells but remains to be proved. On the basis of the probability that ascorbic acid plays a role in the oxidative and metabolic functions of the cell, it may conceivably alter or depress the pressor mechanism considered to be present in the kidney of at least some patients with essential hypertension. More work must be done, since these experiments are suggestive but do not prove that ascorbic acid has an antihypertensive effect in essential hypertension. We are going to try large doses of ascorbic acid in experimental renal hypertension in dogs. There are some reports that vitamin B complex is effective in clinical essential hypertension. I used large doses of the complex in one renal hypertensive dog for two months without obtaining any reduction in blood pressure.

Dr R D TAYLOR, Indianapolis There was no mention of diagnosis in this group of patients. How often and under what conditions were these pressures taken? In a small group of patients isolated blood pressure readings can have no value. Dr E V Allen has recently pointed out the reasons why there are upward of sixty preparations alleged to lower arterial blood pressure. The error of isolated pressure readings was his main point. Have there been any checks of improvement other than arterial blood pressure readings?

Dr W E BROWN, Omaha I should like to ask if there were any blood studies on ascorbic acid, and whether there were any clearance studies to estimate the patient's tolerance for ascorbic acid.

Dr N S DAVIS III, Chicago I am in agreement regarding the wide fluctuations in blood pressure that were mentioned. For that reason I presented cases in which blood pressure readings had been taken by the same individual under similar circumstances over a period of years before the therapy was commenced, in order that its effect might be compared with the blood pressure levels at the same season in previous years. The effects of psychic upsets on the blood pressure level is also shown in some of the records presented. I am planning to study the ascorbic acid blood levels and clearance of such patients before and after treatment is instituted but these studies have had to be postponed.

Treatment of Experimental Renal Hypertension with Vitamin A Concentrate

Dr G E WAKERLIN, C A JOHNSON, PH D, W G MOSS, MS, and E L SMITH, PH D, Chicago We have studied the effect of a vitamin A concentrate by mouth in experimental renal (Goldblatt) hypertension in dogs. Striking reductions in blood pressure were observed in three renal hypertensive dogs treated daily with 200,000 units of vitamin A concentrate in sesame oil by mouth for three months followed by 400,000 units for an additional three months. Two control dogs treated with sesame oil by mouth for six months showed no significant changes in their hypertensive levels. One hypertensive dog has thus far shown no significant change in blood pressure after two months of treatment with 400,000 units daily of a highly purified vitamin A preparation by mouth. Blood serum vitamin A determinations showed good absorption of the purified vitamin A. One hypertensive dog has thus far shown no significant change in blood pressure after two months of treatment with heat inactivated vitamin A concentrate. These incomplete results suggest but do not prove that the antihypertensive activity of the vitamin A concentrate which we have used is due to some heat labile constituent of the concentrate other than vitamin A.

In view of the therapeutic results with the vitamin A concentrate, a study of its prophylactic effect was also made. Thus far 4 dogs have been treated for three months prior to bilateral constriction of the renal arteries with 400,000 units of the concentrate daily by mouth. Two of these dogs developed malignant hypertension following constriction, demonstrating no protection conferred by vitamin A against malignant experimental renal hypertension. The other 2 dogs were not protected against typical benign experimental renal hypertension. Four control dogs were treated prophylactically with sesame oil by mouth. Three of them developed malignant hypertension and the fourth benign hypertension following con-

striction of the renal arteries. These incomplete results again suggest but do not prove that vitamin A concentrate in the dosage used is not effective prophylactically in experimental renal hypertension in dogs.

No evidences of toxicity from the vitamin A concentrate were detected in any of the animals.

The mechanism of the therapeutic effect of vitamin A concentrate in experimental renal hypertension in the dog is obscure. The fact that large doses of vitamin A preparations have been shown to increase the urea, creatinine and diodrast clearances of normal dogs suggests that the vitamin A concentrate which we employed may have altered the pathophysiology of the pressor mechanism produced by renal artery constriction. Obviously the suggestion that the antihypertensive effect may be due to some heat labile constituent of the concentrate other than vitamin A must be investigated further.

DISCUSSION

Dr A C CORCORAN, Indianapolis I have had under observation 10 patients, 9 of them suffering from essential and 1 from malignant hypertension, in 2 arterial pressure decreased 10-15 mm of mercury during treatment with vitamin A but almost certainly from some other causes. There was no subjective improvement in any, and the patient with malignant hypertension rapidly developed renal and circulatory failure. Renal blood flow and filtration rate increased in 5 patients treated for four weeks and in 1 after three weeks, observations after one or two weeks showed no change in 3 patients and after four weeks in 1. Therefore 5 of 6 patients suffering from essential hypertension showed increased renal perfusion after four weeks' treatment. The increase was in 2 observations associated with increased cardiac output due to tachycardia. Clinically, however, the data do not point to the conclusion that vitamin A is of any real value in the treatment of hypertension in human beings even though renal perfusion is usually increased. In terms of body weight the dose we used is roughly one tenth of that used by the authors. It might be argued that a more beneficial effect might have occurred with larger doses and these are being instituted.

Dr L N KATZ, Chicago During the past six weeks 12 dogs with nephrogenic hypertension, 3 of which showed an associated renal excretory insufficiency, were daily given 400,000 units of vitamin A dissolved in fish oil. No drop in blood pressure occurred. I am thus unable to confirm the results reported.

Dr HARRY GOLDBLATT, Cleveland My associates and I also tried vitamin A, but in inadequate quantity, so that the results, although negative, are of no value. We did try carotene (provitamin A) and gave a large dose (400,000 units daily), which is comparable to the amount of vitamin A administered by Dr Wakerlin and his collaborators. This amount of carotene had no effect on the blood pressure of hypertensive animals. There is a question, however, whether carotene in such quantities is absorbed and transformed to vitamin A. Attempts to demonstrate absorption of this material have given negative results.

Dr G E WAKERLIN, Chicago The difference between the results of Dr Page and his co-workers and our own may be explained in several ways for patients. In the first place, they used a different vitamin A concentrate and our results suggest that the therapeutic effects which we have seen in our dogs are not due to the vitamin itself but to some other constituent of the concentrate. It is still possible that essential hypertension in man may not be the same as experimental renal hypertension in the dog, so that what will affect one may not affect the other. We had planned on using carotene but have not done so yet. In view of our results on the 1 dog with highly purified vitamin A we would not expect to get results from carotene. Perhaps the explanation for the failure of Dr Katz's vitamin A preparation to reduce the pressures of his dogs is due to differences between ours and his concentrates in non-vitamin A constituents. None of our therapeutic animals had excretory insufficiency. They all showed the benign type of experimental renal hypertension. So far we have used only 3 hypertensive animals. The fact that we have had therapeutic success in all 3 does not mean, of course, that if we study another 3 or 6 dogs we may not be unsuccessful in all 3 or 6.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Correlation of Functional Changes in Human Stomach

Wolf and Wolff have had an opportunity in a subject with a large gastric fistula to collect at intervals the total volume of secretion in the stomach. An increased parietal cell output was always associated with hyperemia of the gastric mucosa. Hyperemia also accompanied increased motor activity. From the data gathered the authors conclude that when an unusually large volume of gastric juice of high titratable acidity accumulates in an unobstructed stomach during a specified interval it is safe to assume that the mucous membrane is relatively red and that no vigorous contractions are taking place in the

stomach. When under similar circumstances the volume is small and its acidity is highly titratable it is likely that the mucous membrane is relatively engorged with blood and that especially vigorous contractions are taking place. Low acid values with small volumes of gastric juice suggest that the gastric mucosa is relatively pale and that vigorous contractions are not taking place.

Successful Treatment of Gout—Since 1937 Bartels has treated gout with a low purine and fat and high carbohydrate diet with periodic administration of cinchophen. Purine restriction relieves the overburdened purine metabolizing mechanism, the low fat intake prevents purine retention and the high carbohydrate content tends toward the diuresis of uric acid. Cinchophen furthers uric acid elimination. The cinchophen is given in $7\frac{1}{2}$ grain (0.5 Gm) doses three times a day for three days a week. Alcohol is not permitted. When determination of the uric acid every one to three months indicates a reduction in the serum uric acid cinchophen is taken on two days, then one day a week and when the acid reaches a normal or near normal it is withdrawn. The diet is to be followed indefinitely, but if the uric acid continues at a normal level a more liberal diet is given. Acute attacks are treated by the intravenous injection of dextrose in addition to the regimen. Vitamins A and B are added. At times in gouty arthritis physical therapy is helpful and large troublesome tophi are removed. Of 38 patients treated for at least one year 18 have had the disease for more than nine years (average seventeen), 13 for seven years or less and 7 for three to fifteen years. The 7 did not follow the regimen carefully and used alcohol in varying amounts. In the first two groups there was a drop in the uric acid level and further attacks were prevented. After two years of treatment there were only three minor episodes among the 18 as compared to sixty-one major attacks during an equal previous time. The uric acid level which had ranged from 6.3 to 10.2 mg tell to an average of 6.3. Diet and cinchophen were used three fourths of the total treatment time and diet alone one fourth of the time. Among the 13 patients with an average preregimen uric acid level of 7.6 mg there were four minor as compared to twenty-three major attacks respectively during twenty months during and before treatment. Diet and cinchophen was used half the time and diet alone the rest of the time. The 7 patients with an average pretreatment acid level of 8.5 mg had twelve major and four minor attacks during three years of treatment as compared to twenty-three major attacks during the same length of time before treatment. Their average uric acid level fell to 7 mg. Even patients in the phase of chronic gouty arthritis responded to the treatment. The author urges that other physicians consider the plan.

Ileostomy for Chronic Ulcerative Colitis—The 185 consecutive patients who had had an ileostomy for chronic thrombotic ulcerative colitis at the Mayo Clinic from 1913 through 1939 Barger and his co-workers state comprise 5.5 per cent of all patients treated for the disease at the clinic. Eighty-six had undergone ileostomy because of chronic progressive and intractable symptoms, 63 because of severe and fulminating form and 36 primarily because of complications and sequelae of ulcerative

colitis. Thirty-five patients lived less than fourteen days after ileostomy, 20 lived more than thirteen days but less than six months and thus 130 patients remain concerning whom a study of the effect of ileostomy can be made. Of these 130 patients 37 were satisfied, as they were symptom free or had only mild recurrent symptoms of colitis, 42 also were satisfied, as their frequent symptoms of colonic disease were improved, 25 were not improved (they survived for a considerable time but had severe and frequent recurrence of symptoms) and 26 had no benefit from the ileostomy, their symptoms were severe and frequent and they died within a relatively short time after the first six postoperative months. Therefore the incidence of recurrence of infection in the colon after ileostomy is high. Of 18 patients known to be living fifteen or more years after ileostomy, 10 were females and 8 males and their average age at the time of the ileostomy was 32. The average duration of their symptoms prior to ileostomy was four and a half years but varied from one to fifteen. Thirteen had the ileostomy because of intractable symptoms but without severe exacerbations, 4 for an acute exacerbation of the disease and 1 for rectal stricture and persistent symptoms of perirectal infection. Seven of the 18 had undergone colectomy (2 total) after ileostomy. The several factors that seemed responsible for the satisfactory results in this group of patients were that (1) most of the patients had had the disease for a relatively short time, (2) they were young adults and thus were able to adjust their lives to the handicaps of ileostomy, (3) they were operated on for chronic intractable symptoms and not acute exacerbations and (4) the survival of the 7 after colectomy removed in itself the opportunity for any further development or existence of colonic disease.

Blood Sugar and Electroencephalogram.—The electroencephalograms of 40 healthy college students were analyzed by Davis during a routine rest period forty-five minutes after an intravenous injection of insulin (0.05 unit per kilogram), fifteen minutes after the oral ingestion of 50 cc of (Karo) corn syrup and during three minutes of voluntary hyperventilation. There was no consistent relation between the electroencephalographic changes and the pulse rate or blood pressure. As the level of the blood sugar fell to a minimum of 53 to 85 mg per hundred cubic centimeters, the normal alpha activity of the electroencephalogram was increasingly replaced by slower waves, chiefly in the 6 to 8 cycle range. The electroencephalogram returned to normal when the level of the blood sugar was restored, but the changes in the electroencephalogram lagged ten or more minutes behind the changes in the blood sugar. "Slow swings" of two to five seconds' duration often appeared in the frontal record during the height of the insulin reaction. These potential changes apparently originate in the skin of the fore-

head. The conspicuous electroencephalographic changes during the insulin test correlate fairly closely with the appearance of the prominent slow waves during hyperventilation and with the less prominent slow waves in the routine electroencephalogram. Both the insulin test and voluntary hyperventilation apparently accentuate characteristics that are present but less clearly evident in the routine electroencephalogram. The alteration of the blood sugar level does not require the intelligent, active cooperation of a subject and may therefore be applicable for uncooperative or unintelligent subjects. The determination of the effect of the insulin test on the electroencephalograms of abnormal subjects, particularly of known epileptic patients, would be of interest.

Insulin and Epinephrine Tests in Schizophrenic and Normal Subjects.—With the tolerance techniques of Fraser, Albright and Smith, Freeman and his associates investigated the glycemic and cardiovascular effect of insulin and epinephrine on 32 male schizophrenic patients with no physical disease and on 20 normal men. All subjects, 15 to 46 years of age, were studied in a fasting resting state. Half an hour after the injection of insulin the mean value of the blood sugar of the normal subjects decreased to a level of 29.6 mg per hundred cubic centimeters and that for the patients to 39.2 mg. One hour after the injection the respective mean values were 61.1 and 63.6 mg. The indication is that the phase of recovery from the hypoglycemic level was more active in the normal subjects. During the next hour the values for the two groups were similar. Therefore up to this point the trend indicates a greater resistance to insulin, and possibly a less rapid recovery from the hypoglycemic phase, of the patients. Half an hour after the injection of epinephrine the mean for the normal subjects rose 26.1 mg and in one hour 52.7 mg per hundred cubic centimeters. The corresponding increases in blood sugar for the patients were 22.5 and 40 mg. The response to exogenous epinephrine was definitely less in the patients, this seems to corroborate the previous observation of a probable lessened reactivity to endogenous adrenal activity. In general the changes in the blood pressure and pulse rate were greater in the normal subjects, they paralleled the differences in the blood sugar between the two groups.

Cerebral Dysrhythmia in Relation to Eclampsia.—According to Rosenbaum and Maltby, the electroencephalograms of 65 per cent of 20 patients with eclampsia were indicative of cerebral dysrhythmia as compared with 2, or 10 per cent, of 20 patients with preeclampsia. Twelve of the patients with eclampsia had a family and personal history of convulsive disorders, while only 2 of the preeclamptic patients had a similar history. It is suggested that a primary cerebral dysrhythmia may be present in patients with eclampsia and that the associated toxemia may be the "trigger mechanism" that exaggerates the inherent dysrhythmia to the degree that convulsions appear. A careful history with an electroencephalographic study might aid in predicting the development of eclampsia. The prophylactic therapy of eclampsia may include the use of anticonvulsant drugs.

Ureteral Stricture and Bright's Disease—Hunner has previously traced the evolution of the concept that ureteral stricture may be an important etiologic factor in the development of many cases of Bright's disease. In his experience it has seemed to occur so often that a thorough examination of renal drainage cannot be claimed without a searching investigation, including the bulb test. The symptoms typically associated with ureteral stricture are similar to those of the early stages of Bright's disease. Many of the more pronounced symptoms of the disease, such as persistent headache slow mental function inability to tolerate a sufficient amount of nourishing food and even recurrent convulsive seizures and coma have yielded promptly to the establishment of good renal drainage. Many patients have experienced this phenomenal improvement after prolonged treatment by other measures failed. The author could not account for the beneficial results obtained by his 9 patients on any basis except that better renal drainage was established. None of the patients had a prolonged rest period in the hospital, except when an operation was needed for some associated secondary complication. None of those with renal infection were given antiseptic drugs. Each was allowed

to choose his diet. Most of them were soon able to resume their regular work. The condition of 1 patient a pregnant woman, was considered only potentially as Bright's disease. Without drainage the patient would have aborted and in all probability would have remained an invalid. At the end of four years she was in excellent health, having carried to term an uncomplicated pregnancy fifteen months before. Three patients engaged in fairly normal activities for five six and nine years respectively or until death after the ureteral obstruction had been identified and dealt with. Before, it was doubtful whether any of these 3 patients would have lived for even one year if adequate renal drainage had not been established and maintained. The remaining 5 patients are still on the active list for twenty-one, twenty-six, twenty-five, sixteen and twenty-five years respectively after their first treatments. Their average age is now about 62 years. The author believes that not 1 of these 5 persons would be living today had they been dependent on the traditional methods of urologic treatment.

Endocrine Treatment of Cancers of Prostate—During the last eleven months Dean and his colleagues have used estrogen in the treatment of 60 patients with carcinoma of the prostate. In their experience surgical castration almost invariably has spectacularly relieved patients with prostatic cancer. Only 2 men failed to show improvement. Almost without exception pain disappeared within forty-eight hours appetites became remarkably good, body weight increased rapidly, strength returned and some of them resumed their former occupations. Eight patients who were able to tolerate 2 to 5 mg of diethylstilbestrol daily were generally improved, the improvement was as great as that following orchiectomy although possibly somewhat slower. Under diethylstilbestrol the size of the prostatic tumor appeared to diminish regularly and the amount of residual urine decreased. The conformation of the bodies of some of these men became feminine. There were no relapses although 1 patient failed to respond favorably. From the research point of view it seems that the natural history of prostatic cancer may be definitely modified by changes in the endocrines, which changes can be produced by surgical castration as well as by the oral administration of estrogens. From this starting point not only the cure but probably also the prevention of prostatic cancer can be brought about by the clinician working in collaboration with the biochemist.

Mysterious Mixed Tumors of Salivary Glands—McFarland has collected approximately 400 cases of mixed tumors of the salivary glands—that is, the parotid, the submaxillary and the sublingual—that were seen at various hospitals in and around Philadelphia during more than twenty-five years. His method of finding cases is to examine microscopic slides of salivary gland tumors as may have accumulated in the laboratories, to select the ones that conform to the taxonomic requirements and then to review the protocols for the essential clinical information. Some 200 patients in six Philadelphia hospitals were operated on by seventy-three surgeons. The microscopic structure of these tumors is extremely variable. Harvey, Dawson and Innes made use of fifty-four photomicrographs to explain the variation of their appearance. With such complexity it may become difficult to decide whether a given tumor is a mixed tumor or not. The inclusion or exclusion of such tumors must depend on the theory of origin to which one inclines. If one follows Cuneo and Veau and Chevassu in believing that the tumors arise through the "enclavement" of embryonal substance in the developing face and neck, they may be retained, if, on the other hand, the origin of the tumors from neoplasia of the respective salivary glands is accepted, they must be eliminated. The author's studies agree with the latter, now popular, view. His analysis of the infiltrative growth, local destructive properties, recurrence, metastasis, local interference with function and general toxic action of absorbed tumor products leaves him in some perplexity as to whether mixed tumors are malignant or not. A good deal of this is the result of the different terminology used by pathologists. It might be best to say that they are mixed tumors and will probably recur. There has been an occasional recurrence twenty, thirty and forty years after operation. In mixed tumors postponing surgical intervention ordinarily has everything in its favor. It is wiser not to operate as long as the patient is willing to wait. It seems useless to attempt to control or modify the growth of the tumor or to

postpone its recurrence by the use of x-rays or radium. Supposed indications for complete surgical excision are the embarrassment caused the patient by the disfigurement, limited and difficult movement of the mandible, pain from pressure on the sensory nerves and a sudden and rapid increase in the size of the tumor. If the tumor is a mixed tumor, rapid growth usually supervenes after it has existed for years. If the tumor is a carcinoma, its excision usually fails to afford much benefit, as the patient dies regardless of treatment. As for results of treatment among the author's series of collected cases at least half of the recurrences were and many still are believed by their surgeons to have been cured. Doctors fail to follow up their patients, forgetting that as many as forty years may elapse before a recurrence presents itself.

Surgical Treatment of Carcinoma of Colon and Rectum—Since July 1937 Garlock, Ginzburg and Glass state that they have had the opportunity to study 6 cases of cancer of the cecum, 16 of the ascending colon and 8 of the hepatic flexure. Frequently two or three weeks was taken preoperatively to overcome anemia, nutritional and vitamin disturbances and to treat renal complications and cardiovascular disabilities. The condition of only 13 patients permitted operation at the time of exploration. Operability was influenced more by conditions associated with the growth than by age, obesity and anemia. Free perforation of a carcinoma of the colon is a lethal complication in most instances. The Miller-Abbott tube was used often with obstructing lesions. The preoperative oral administration of sulfanilamide was a greater factor in decreasing the incidence of postoperative infection of the wound and peritonitis than its local use at operation. Postoperative pulmonary complications were beneficially influenced by the sulfonamides. Cardiovascular complications were the major cause of postoperative morbidity and mortality. Wound disruption was curtailed by the use of buried alloy steel wire. A rarely mentioned postoperative complication was retraction within the abdomen of a loop of intestine. For carcinoma of the right colon two stage ileocolic resection, with a three or four week interval between the procedures, is favored, and obstructive resection with wide excision of the mesentery for neoplasm of the transverse and left colon. Suture anastomosis of the left colon should not be done unless the fecal current has previously been completely diverted. For small carcinoma of the rectosigmoid the preference is the Devine operation, for carcinoma of the rectum the one stage Miles abdominoperineal resection and for low-lying neoplasm in the elderly the Lockhart-Mummery procedure. Finally, between 20 and 25 per cent of the patients had undergone treatment for hemorrhoids during the preceding two to five months, thus the importance of a carefully performed digital-rectal examination and proctoscopic visualization of patients complaining of bleeding from the rectum is certainly apparent.

Blood Substitutes in Resuscitation After Hemorrhage—After massive hemorrhage in animals Ivy and his colleagues found that recovery was prompt though temporary of most animals given injections of saline solution. The procedure has value in case of emergency, with the obvious necessity of further treatment with a more potent preparation as soon as possible. In the latter category may be placed heparinized plasma or serum. Regarding gelatin (plasma gel), the material used was definitely superior to citrated plasma and to the other artificial blood substitutes tested, but it fell far short of perfection. All but two gelatins studied caused definite pseudoagglutination of erythrocytes. If a gelatin can be found which will cause no pseudoagglutination, it will prove to be a good blood substitute for emergency use. Plasma gel was not suitable. The high toxicity of citrate when given in the amounts required as an anticoagulant for the large volume of plasma required under the experimental conditions is a contraindication for its use when hemorrhage is extensive. The great superiority of heparinized plasma over serum is at present obscure. It is obviously not due to the fibrinogen in the one and its absence in the other, but more likely to certain alterations in the protein content which occur during the preparation. Acacia and pectin are totally unsuitable as blood substitutes when the hemorrhage is extensive.

Relation of Maternal Diet to Breast Feeding—Ebbs and Kelley compare the incidence of successful breast feeding among three groups of mothers of the low income class. The 90 women who were supplied with extra food (milk, eggs, cheese, fruit and vitamins) and the 170 who were educated to provide a good antepartum diet were more successful in nursing their infants than the mothers who had been left on their poor antepartum diets. The effect of a poor postpartum diet on nursing was evident by a decrease in the percentage of breast fed babies when extra food was stopped six weeks after the birth of the baby. This sudden decrease might be explained by the change in mental attitude of the mother when the supplementary food was withdrawn or it might have been the result of the sudden withdrawal of certain food factors which possibly influence the secretion and the quality of breast milk.

Mortality of Breast and Artificially Fed Infants—Among the 1500 infants less than 1 year of age admitted to the Hospital for Sick Children, Toronto, with infection Ebbs and Mulligan observed that fewer so affected were breast fed than artificially fed. The incidence of breast feeding among these 1500 infants with infection was less than half that in the well baby clinics of the city. Respiratory infections were more frequent than other infections. The incidence of gastrointestinal infection was lower among the breast fed babies. The mortality rate was slightly higher among the breast fed group.

Irradiation of Wounds and Inflammation—Finzi and Freund believe that the use of radiation in the treatment of war wounds is extremely valuable and that the use of the method will without doubt increase much in the future especially when experience has confirmed the good results which could not have been achieved by other means. Acute subacute and chronic inflammation may be treated by small doses of γ -rays. Irradiation accelerates the healing of wounds and fractures. The effect of γ -rays is due to their influence on local cellular reaction and local immunity. Small doses give good results and obviate late bad effects.

Sulfaguanidine in Bacillary Dysentery—Brewer treated 77 cases of bacillary dysentery with sulfaguanidine. The drug was used only in severe or refractory cases. Patients were put to bed at rest and kept warm. The frequency and character of their stools were noted and specimens were plated and examined microscopically. Diet was limited to fluid in the first twenty-four hours. A large oral fluid intake was encouraged to replace fluid loss. No fluid intravenously was necessary. Adjunct treatment was given: the 36 patients with Shiga intoxication were given 30 000 units of antiserum. The patients with an acute infection were given an initial dose of 7 Gm of sulfaguanidine followed by 3.5 Gm every four hours. For severe infection 3.5 Gm was given in two hours after the initial dose followed in two hours by a further 3.5 Gm. In the main sulfaguanidine was given for two days after the stools had become normal. Patients with chronic infection received 17.5 Gm of sulfaguanidine daily in five doses for a minimum of eight days. The length of treatment was increased in the severer cases. A preliminary period of treatment with colonic lavage while on a low residue diet was had by 19 patients. In chronic cases sulfaguanidine must be given until the mucosa has healed, to gauge this sigmoidoscopy is essential. Complete cure was obtained in 19 (73 per cent) of the acute cases, in 11 (55 per cent) of the chronic cases in which 90 Gm was given over six days and in 24 (77 per cent) of the chronic cases in which an average dose of 160 Gm was given over ten days. Toxic symptoms occurred in only 9 of the 51 chronic cases.

Reflex Governing Flow of Milk—To estimate the frequency of breast engorgement and its consequences, Waller questioned 52 consecutive women at an infant welfare center within four weeks of their confinement. All but 4 had been delivered in a hospital. No woman with an abnormal pregnancy, labor or puerperium was included with the exception of 3 who had mastitis. Twenty-two at four weeks were still breast feeding their babies and 30 had already ceased to do so. To the first question, whether their milk was plentiful in the first week after delivery, 46 replied affirmatively. Damage to the nipples was experienced by nearly three fourths of those who failed to continue breast feeding and in more than a third of the successful ones. Failure to withdraw milk (21 babies) which might be attributable to weakness in the baby was more common with the first born. There was overloading of the breasts in 34, and relief by breast pump was obtained by 27. The data suggested that the common tendency of the breasts to become overfull at the outset involves a risk to the continuance of milk secretion, that the risk of arrest is greatest in the first lactation and that the child's demands for food are unreliable as a means of reducing a state of high breast tension to a level ensuring continuance of secretion of milk. The emphasis is not directly on any particular degree of fullness but on the degree of emptiness to which the breasts are reduced when the child has finished feeding. Certain facts suggest that outflow is dependent on a reflex mechanism highly susceptible to interference and conditioning. The maintenance of secretion appears to depend on a reflex expelling mechanism which governs the outflow from the breast and which for convenience may be called the draft reflex. When the reflex is interfered with a baby who has learned to rely on its assistance may refuse to attempt to obtain milk. It more was known of the nature of the reflex many of the common hindrances to lactation might be brought under control. The draft reflex which is so characteristic a feature once feeding is established does not seem to be operatively effective when the breasts first begin active secretion a time which seems particularly appropriate to its appearance. In multiparous women who have successfully nursed their babies secretion and expulsion sometimes coincide. In primiparas the reflex is present must often be frustrated almost at once. In them the breast often seems incapable of achieving a balance between secretion and outflow so that stasis and overloading result. The author believes that a satisfactory reduction in the number of early failures will be seen only when initial overfilling of the breasts is prevented or at least lessened and it can be ensured that the draft reflex comes promptly and effectively into action.

Poisoning by Chlorinated Naphthalene—Since the Home Office has included poisoning by chlorinated naphthalene and its sequelae in the workmen's compensation act Collier declares that it is important for general medical practitioners and especially industrial medical officers examining factory surgeons and medical referees to know the toxic effects that it can pro-

duce Twelve illustrative cases of dermatitis and 1 of acute yellow atrophy of the liver among workers in an engineering establishment exposed to the fumes and dust of chlorinated naphthalene are reported. Poisoning by chlorinated naphthalene may result in chloracne of the face, particularly of the sides of the face. If it produces systemic effects (acute yellow atrophy or necrosis of the liver) the liver is usually the only organ damaged. If poisoning is to be prevented, the wax must not be overheated and its fumes and dust must be properly carried away by exhaust ventilation. Workers must be instructed in the importance of personal cleanliness and must be examined every week for signs of acute or jaundice.

Extracts of Endometrium and Ovarian Function—At Werner's clinic in Vienna, Borris had observed the implantation of inserts of endometrium into the remaining uterine stump in order to reduce the menopausal reactions after hysterectomies. Employing the method himself he found that, while in some cases it exerted a real influence, in others the effect was hardly visible and he came to the conclusion that the endometrial implantations into the stump could not solve the problem, the more so since endometriosis resulted in one of his patients. Supposing that extracts of the endometrium would exert a substitutional effect, the author obtained and injected bovine extracts. He describes the difficulties encountered in obtaining them, since it was found that the endometrium had to be obtained from animals in estrus. He also reports clinical trials with different concentrations. The menopausal disturbances of the hysterectomized who still have their ovaries are less intense if they are given periodic injections of endometrial extracts, and women with ovarian insufficiency who need monthly fixed doses of estrone can get along with smaller doses of estrone if endometrial extract is injected fifteen days before the expected menstruation. The clinical results so far obtained are not entirely satisfactory, but the author thinks that it is merely a question of dosage, which is under investigation.

Revista Médica de Chile, Santiago

70 833-931 (Nov) 1942 Partial Index

- *Chronic Manganese Poisoning Two Cases M Kaffman, J Oyarzun and E Concha—p 892

Clinical Experiences with Hanger's Reaction—Alessandri and his associates used Hanger's test, which employs the flocculation of cephalin-cholesterol emulsions in order to differentiate obstructive from hepatogenous jaundice, in several groups of patients. In performing the cephalin-cholesterol test on 72 apparently normal subjects they found that as a rule the reaction was negative, rarely it was doubtful and exceptionally, that is, in persons with a history of dyspeptic disturbances or with a previous attack of jaundice, it was mildly positive. Hanger's test performed on 75 patients with catarrhal jaundice revealed positive flocculation in 69 (92 per cent). In a few cases, which showed rapid improvement, the reaction became

negative rather early and confusion with mechanical jaundice is therefore not likely. The flocculation reaction runs parallel neither with the functional tests of the liver (tolerance, for carbohydrates and for sodium benzoate) nor with the cholesterol content of the blood. In the majority of cases of catarrhal jaundice the positivity of Hanger's reaction decreases parallel with the clinical improvement and with the decrease in the bilirubinemia figures. The third group of patients on whom the authors made the cephalin-cholesterol test were 12 persons in whom jaundice was produced by arsenotherapy. Positive flocculations were obtained in the majority of these cases, which indicates involvement of the hepatic cells. Negative reaction in a few early cases seem to speak for an obstructive factor. The cases of obstructive jaundice in which the authors performed Hanger's test comprise two groups. 1 Of 14 cases in which the obstruction was due to neoplasms 11 had negative reactions, 2 had mildly positive reactions and 1 had an intensely positive reaction, the last patient had a severe hepatomegaly. 2 Of 16 cases in which choledocholithiasis was present the reactions were negative in 10, mildly positive in 3, moderately positive in 1, intensely positive in 2 and doubtful in 1. The cephalin-cholesterol flocculation proved highly positive in all of the 17 patients with hepatic cirrhosis. The authors conclude that the cephalin-cholesterol flocculation is easy, is low in cost and can be performed in any clinical laboratory. It merits to be incorporated in the routine study of patients with digestive disturbances. Although it is not infallible in the differential diagnosis of icteric disturbances, it nevertheless represents a valuable aid. If it is strongly positive in recent jaundice, involvement of the hepatic cells exists, if it is negative in a jaundice that drags on for months, mechanical icterus should be thought of. It is positive in over 95 per cent of the cases of parenchymatous impairment of the liver and, if this damage is severe, positivity of Hanger's test reaches 100 per cent.

Lateral Pyelography in Surgical Disorders of Kidney—Donoso thinks that lateral pyelograms should be made, if possible, by the retrograde route, that is, by ureteral catheterization. Only when catheterization is not possible should the descending, intravenous method be employed. After the anteroposterior pyelographic exposure the patient is turned on the side. The kidney to be examined should be next to the film. The author describes a number of cases in which he employed the method and reproduces roentgenograms. Lateral pyelography has a wide field of application. The technic is simple and does not greatly disturb the patient. The interpretation is easy. It makes possible otherwise difficult and obscure differential diagnoses. It permits the differentiation of neoplasms, cysts or collections of pus, whether they are renal, perirenal or extrarenal. It reveals primary or secondary retroperitoneal neoplasms, tumors adjacent to the kidney and metastases of malignant tumors. It aids the differentiation between urinary and biliary calculi, shadows of calcified lymph nodes, traumatic renal lesions, congenital pelvic deformities and ureteral stenosis.

Chronic Manganese Poisoning—Kaffman and his associates describe manganese poisoning in 2 men aged 27 and 42. One had worked in a manganese mine for eight months, the other for a year and a half. Like the other 200 workers in this manganese mine, these men had done their work in an atmosphere charged with mine dust, none of the workers were wearing protective masks. Both patients presented the symptoms typical for manganese poisoning. The first manifestations usually involve the motor apparatus, particularly the walk, which becomes incoordinated. The facial expression becomes masklike, the voice monotonous. Mental impairment varies, it shows itself in indifference, in lack of attention, in amnesia, in somnolence and at times in attacks of excitation. The younger of the 2 patients showed the first signs of manganese poisoning after he had worked in the mine for only five months. The evolution of manganese poisoning varies. In some cases the symptoms regress after contact with manganese ceases, in others the damage is permanent. In 1 of the reported cases there was slow but noticeable improvement a month after the work in the manganese mine had been given up, in the other 1 the mental changes subsided rapidly but not the other symptoms. The authors stress the great importance of prophylactic measures in manganese mines.

Book Notices

Indigestion Its Diagnosis and Management with Special Reference to Diet. By Martin F. Rehfuess M.D. Professor of Clinical Medicine Jefferson Medical College Philadelphia. Cloth Price \$7. 1 p. 556 with 63 illustrations. Philadelphia & London W. B. Saunders Company 1947

This is an attractive looking book which is well printed and well illustrated. It is likely to be of much interest to the general practitioner, for whom it has been written, because it shows with pictures and descriptions how a number of the common procedures in diagnosis and treatment are carried out. One difficulty about the book is that Dr. Rehfuess tried to cover such a large field that some of the chapters cannot be adequate. One cannot help wishing that the chapter on gastrophotography had been left out and the space given to other subjects such as history taking or nervous indigestion. Psychiatrists would probably question Dr. Rehfuess's advice to administer mixtures of several medicines to patients with nervous indigestion. Most psychotherapists maintain that if one expects to cure a neurosis one must not counteract the effect of telling the patient that he has no organic disease by giving him a lot of medicine for it. A few gastroenterologists might wonder also how far one can hope to get with the dietary treatment of gallstones. There is much good advice in the section on dietetics at the end of the book. It is good to see that Dr. Rehfuess puts little stock in the diagnosis of chronic appendicitis. As he says, shortly after the consultant has told a patient that he has a pure neurosis the man or woman may write to say that a surgeon has just worked a cure by removing the appendix, but then the consultant must not be too disturbed until at least six months have elapsed. By then it will usually be found that the symptoms have all returned. On the whole, this book can be recommended as a good addition to the library of the general practitioner and the gastroenterologist.

A Doctor Without a Country By Thomas A. Lambie M.D. Sc.D. FR.G.S. Field Director of Sudan Interior Mission. With an introduction by Howard A. Kelly M.D. F.A.C.S. LL.D. of Johns Hopkins University Baltimore. Second edition. Cloth Price \$2. Pp. 252 with 7 illustrations. New York London & Edinburgh Fleming H. Revell Company [1942]

A Doctor Carries On By Thomas A. Lambie M.D. Sc.D. FR.G.S. Field Director of Sudan Interior Mission. Cloth Price \$2. Pp. 173 with one illustration. New York London & Edinburgh Fleming H. Revell Company 1942

These books were written by an American doctor who has spent many years as a medical missionary in the Sudan and in Ethiopia. They contain much interesting geographic, ethnologic and climatologic information through which permeates a strong religious flavor. The chapters which pertain to Ethiopia are particularly interesting. The author lived in Addis Ababa, where he became the adviser of Emperor Haile Selassie. He established the Sudan Interior Mission and the George Memorial Hospital which is named in honor of W. S. George of East Palestine, Ohio, who gave some \$70,000 toward its construction. Among the various diseases present was typhus some victims of which they picked up on the streets and took to the hospital. Dr. Lambie says that cancer and appendicitis were almost never seen in Abyssinia or anywhere in tropical Africa. It was necessary to give up his American citizenship and to become a citizen of Ethiopia. When the Italians invaded that country in 1935 the author became the executive of the Ethiopian Red Cross. Addis Ababa was filled with wounded and retreating soldiers whose condition was pitiable. Dr. Lambie was close by when the emperor and his court fled the capital, not long thereafter he too left Ethiopia and ironically, in coming home to America he became a doctor without a country.

The second book deals with the author's return to Africa in 1939 where he again became engaged in medical missionary work. He was of some service to the British army during the Ethiopian campaign, which ended in driving the Italians out of the country. At times these books remind one of the exploits of the great African explorers Dr. David Livingstone and Sir Henry Morton Stanley.

An Evaluation of Dental Health Literature By Vern D. Irwin D.D.S. M.P.H. Director and Netta W. Wilson M.A. Educational Assistant Division of Dental Health Minnesota Department of Health. With a foreword by Frank C. Cady D.D.S. M.P.H. Senior Dental Surgeon United States Public Health Service. Approved by the American Association of Public Health Dentists. Paper Price 50 cents. Pp. 38 with 1 illustration. Saint Paul & Minneapolis Bruce Publishing Company 1942

This is an exceptionally valuable contribution to the literature of health education. It makes a dual contribution. First it gives a much needed evaluation of dental health literature and clarifies many inaccuracies. Second it furnishes a pattern for similar evaluation of health education literature in other fields which might well be undertaken by persons as well qualified, for example, in nutrition, communicable disease control and personal hygiene as are the authors of this evaluation in dentistry.

Without going into detail as to the numerous fallacies, controversial statements, half truths and downright errors occurring in dental literature issued not by advertisers, quacks or promoters but by reputable health education groups, it is sufficient to point out here that the authors based their survey on a large number of sources of which they list seventy-six state health department bulletins, twenty-four publications of the American Dental Association and five miscellaneous publications, including one each of the United States Children's Bureau and the United States Public Health Service, in all of which dental errors, inaccuracies or controversial statements have appeared. In addition, twelve textbooks and twelve magazine publications, including both lay and professional magazines, are listed.

Among 235 statements published before July 1, 1940 and representing the first 235 statements examined, they found 74 to be facts, 57 to be fallacies and 104 controversial. Of the last 145 statements examined, mostly published after July 1, 1940 they found 57 to be facts, 8 to be fallacies and 70 to be controversial statements. They published extensive statements which they considered to be subject to criticism, and opposite each such statement appears their comment and evaluation.

An excellent chapter is that on adaptation of dental health literature to the audience with special reference to material for children. They object to efforts to make children brush their teeth by comparing them with good little rabbits, who obviously never brush their teeth at all. They object to health advice which may be good, bad or indifferent as to rhyme but is mostly bad as to accuracy. They also pay their disrespects to dental health plays in which fallacious implications are carried.

Every health educator or any one else who communicates with the public about health matters should read and digest this evaluation.

So You Feel Sluggish Today The Causes and Treatment of Constipation By Harry Gauss M.D. Assistant Professor of Medicine University of Colorado Denver. Cloth Price \$3. Pp. 291 with 38 illustrations. Boston Christopher Publishing House 1942

According to the introduction this is intended to be a book "at once instructive to the physician and intelligible and therefore helpful to the layman." It is fair, therefore, to evaluate the book on this basis. The number of instances in which it has been possible to write one book for common use of doctor and layman is so small that each instance is a noteworthy book of permanent value. This book does not achieve that distinction. It is far too elementary for the physician and far too technical for the layman. The book starts out with a descriptive anatomic chapter of thirty-one pages. The rest of the book exclusive of glossary is devoted to lengthy, tiresome and repetitious discussions of various factors in the causation of constipation. The effect of all this material on the normal lay reader would be that he would simply rebel against it and toss the book aside. The introspective person with constipation however would seize on this book and find it full of fresh fuel for all his anxieties real and imaginary. Particularly pernicious is the twenty-three page chapter "Check Your Symptoms" which will be a paradise for the hypochondriac. The twenty page detailed chapter on laxatives "When and How to Use Them" is an invitation to self medication. Since many of the troubles of the constipated are aggravated or not caused by too much concentration on the eliminative function all these pages on constipation is just too much.

Nurses in Action The Story of the Army Nurse Corps By Colonel Julia O. Fluke, A. S. Superintendent of the Army Nurse Corps. Cloth. Price \$2.50. Pp. 239. Philadelphia: New York & London: L. B. Lippincott Company, 1943.

I Served on Batran By Maunila Redmond, Lieutenant. A. N. C. Cloth. Price \$1.75. Pp. 167 with 16 illustrations. Philadelphia & New York: L. B. Lippincott Company, 1943.

At this time when the recruitment of young women to qualify as nurses for our armed forces is at its peak these two books are exceedingly welcome. They will do much to aid in the campaign and to enlighten people as to the tremendous service that our nurses render.

Col. Julia O. Fluke is superintendent of the Army Nurse Corps. Her book begins with the decision of a young girl to qualify for the Army Nurse Corps and tells the first steps in such qualification. Then come a brief history of the Army Nurse Corps, an outline of the technique of entrance into the service, and several sections devoted to the work of the army nurse and to army nursing as a career. The final section is a description of the Army Nurse Corps, the medical and hospital service of the Veterans' Administration and the Indian Service. The book is up to the minute with illustrations which are taken from current war files. Colonel Fluke is the first woman ever to hold the rank of colonel. She served in World War I and during the following years today there are nurses under her command throughout the world. The volume is authentic, factual and written in a style suitable to the student or to the reader who is interested only in general information.

Lieut. Maunila Redmond was one of the few who escaped from Batran and Corregidor. When Maunila was declared an open city, Lieutenant Redmond went into the jungles of Bataan with other nurses and doctors to set up a hospital. The story of Bataan has been told many times but never more effectively, more sympathetically or more interestingly than it is here told by Lieutenant Redmond. Physicians will find her accounts of gas gangrene and medical care under siege conditions stimulating and informative. Every reader will be moved by this account to do his utmost and then some as a contribution in this war.

The Hospital Care of the Surgical Patient A Surgeon's Handbook By George Crile, Jr. M.D. Surgeon, Cleveland Clinic, Cleveland and Franklin I. Shively, Jr. M.D. Assistant Surgeon, Cleveland Clinic. Foreword by J. V. A. Graham, M.D. Bishop Professor of Surgery, Washington University School of Medicine, St. Louis. Fabrikoid. Price \$2.50. Pp. 184 with 21 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

This first edition by Crile and Shively is a concise, clearly written handbook especially designed for the young physician who is about to begin his training in the field of surgery. The authors have emphasized the application of our knowledge of physiology and biochemistry to the routine preparation of the patient, the operative procedure, the postoperative care and the recognition and treatment of complications. A word regarding prophylaxis against pulmonary complications and embolism would have been of value. The reviewer sought the reaction of several surgical residents to this book and they all agreed that the book was interesting and instructive. The one objection to a book of this kind might be brought against any textbook, and that is that our knowledge of physiology, biochemistry and chemotherapy is increasing and ever changing, and portions of this book may require revision soon. The surgical residents at other hospitals and clinics will also find that the preparation and treatment of the patient vary greatly from certain routine procedures advocated in this book, but naturally it was not the aim of the authors to include all routines. This handbook is recommended to those who are about to begin their graduate study of surgery, and they will find it an "aid in effecting a standardization of hospital treatment."

Index Catalogue of the Library of the Surgeon General's Office United States Army (Army Medical Library) Authors and Subjects Fourth Series, Vol. VII H H YSTRIX Cloth. Price, \$2.75. Pp. 972. Washington, D. C.: Supt. of Doc. Government Printing Office, 1942.

This volume on the letter H of the justly famous Index Catalogue consists of 972 pages. The Army Medical Library now contains over 400,000 volumes and 624,000 pamphlets of all sorts. This volume continues the high standards of the compilers of this publication.

The Metabolic Cost of Maintaining a Standing Position with Special Reference to Body Alignment By Harriet Graham McCormick. Paper. Price \$1.25. Pp. 75, with 9 illustrations. Morningside Heights, New York: King's Crown Press, a division of Columbia University Press, 1942.

This monograph reports clearly a study on the subject mentioned in the title and outlines in detail the methods employed. The work was done thoroughly and accurately. The results are presented in full, and conclusions are stated conservatively. A bibliography of eighty-five items is the background for a critical and thoughtful discussion of work related to the problem under investigation. The alignment associated with the minimal metabolic increase is, as might have been expected, a slovenly posture. The authors question whether this is to be advised because it is maintained primarily by ligamentous action and because it is inefficient "as a starting position and basic underlying pattern for movement." The alignment associated with the maximum metabolic increase was found to be roughly the posture assumed by the military at the command of "attention." Probably, the authors suggest, the ideal is somewhat between these two extremes, a posture which gives the maximum return for a minimal energy expenditure. This posture is one in which the angles formed with the vertical by the lower leg, the upper leg and the trunk are near zero. In other words, one in which the center of gravity of each section of the body is maintained in approximately the same vertical plane. The posture of different persons depends not only on habit early formed but also, no doubt, on variations in origins and insertions of muscles and ligaments. There is no ideal standard of posture which should be applied rigidly to all persons.

A Review of Medicine by Members of the Faculty, Northwestern University Medical School Edited by Benjamin Boshes, M.D., M.S., Ph.D. Assistant Professor of Nervous and Mental Diseases, Northwestern University Medical School, Chicago. Fifth edition. Cloth. Price, \$9.50. Pp. 712. Chicago: Northwestern University Press, 1942.

This book is an outgrowth of the "Lectures of the Cook County Hospital Quiz Course," which are given to medical students preparing for the competitive examinations for internship in the Cook County Hospital, Chicago. Many subjects in medicine, surgery, obstetrics and gynecology, pediatrics and special fields are discussed briefly in outline form: etiology, pathology, symptomatology, complications, differential diagnosis, prognosis and treatment. This form occasionally gives rise to mild absurdities such as that under treatment of heart disease, where the first two entries under the subhead "Active Treatment" are "Absolute Bed Rest" and "Sleep." The book contains a great deal of simply presented information on many disease conditions. It will appeal to those who like to study according to the outline or quiz method.

Medical Jurisprudence and Toxicology By John Glaister, M.D., D.Sc. Fellow of the Royal Faculty of Physicians and Surgeons, Glasgow. Seventh edition. Fabrikoid. Price \$8. Pp. 671 with 132 illustrations. Baltimore: William Wood & Company, 1942.

Seven editions since 1902 indicate the extent to which this book has become a classic in British medical jurisprudence. The book follows the British rather than the American approach to the subject, although numerous references to recent American literature are included. A special section of the present volume relates to the war, with the forms used in England for reporting war injuries. Here the material devoted to the effects of blast is already quite obsolete. The concentrated character of the volume makes it necessary in many instances to limit the discussions almost to definitions. As a reference work on modern medical jurisprudence the book is quite adequate.

Interviewing Its Principles and Methods By Annette Garrett, Associate Director, Smith College School for Social Work. Paper. Price \$1. Pp. 123. New York: Family Welfare Association of America, 1942.

This monograph on the subject of interviewing is already in its second printing. It deals with the technique of interviewing persons who may be reluctant to talk by reason of shyness or antagonism and those who may be overanxious to talk for reasons of their own. Many examples are given of successful interviews together with discussions as to the reasons for their success. It contains many points which might be helpful to the physician, especially in relation to history taking.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HAZARDS OF EXPOSURE TO GLASS WOOL, GLASS FRIT OR FOAM GLASS

To the Editor—Can you give me any information as to the hazards to the health of workers employed in the making of glass floss?

Jean Henderson MD Stamford Conn

ANSWER—The term 'glass floss' is a nondescript one variously applied to glass wool to 'toam glass' and to the 'glass frit' as used in porcelain enamels. The manufacture of the last named entails the greater exposures since common frits may contain lead, silica, fluorspar, cryolite, nitrates, antimony and the like. Further, colored frits may contain selenium, cadmium, chromates, uranium or manganese depending on the color desired. Some of these enamel frits long have been regarded as a frequent source of lead poisoning. However, it seems more likely that this inquiry refers to glass wool or fiber glass. The process of manufacture differs with the ultimate use contemplated such as the manufacture of glass silk for garments, diving suits, coverings for machinery or instead glass pads for air conditioning, insulation, refrigeration or laboratory usage. All further comment is limited to the latter and coarser process. Glass to be reduced to the 'wool' state is already made although the composition may be dissimilar to ordinary glass. The starting point for 'glass wool' is the remelting of this glass. Furnaces are so constructed that when suitable temperatures are reached the molten glass may be discharged through a sieve-like structure. The strings of glass immediately are blown on with live steam or air under pressure. The result is a disintegration of the glass strings into minute fibers lying somewhat in parallel lines in the direction of the air blast. Since the process starts with preformed glass the usual exposures of glass manufacture may be eliminated. The remaining and specific exposures may be three in number and are (1) the usual ill effects of high temperatures, (2) mechanical injuries from spicules of glass or (3) carbon tetrachloride or ether vapors which chemicals are sometimes used to remove a mineral oil lubricant at times applied to the glass fibers to promote disentanglement. Any handling of fibrous glass may lead to the penetration of the skin by numerous minute glass particles. This may lead to isolated, slow healing minor furuncles or a more diffuse dermatitis. For the purpose of lubrication a light mineral oil may be applied to the mass of glass wool in connection with its 'combing'. Later this must be removed through the use of some oil solvent of which carbon tetrachloride is but one example. Although Schulz (Gasmasker 11:57, 1939) mentions an asbestosis-like condition of the lung of a man working with glass wool, it may be doubted that any specific pneumoconiosis is likely to arise. A publication entitled *Sate Practice in the Manufacture and Usage of Fibre Glass* being *Sate Practice Bulletin No. 58* of the Pennsylvania Department of Labor and Industry, February 1940, furnishes extensive information about the exposures incident to this industry.

VERTIGO IN PATIENTS WITH HYPERTENSION

To the Editor—Is there any treatment that relieves vertigo in cases of hypertension especially among the aged when reduction in the blood pressure does not give relief from the vertigo?

MD Illinois

ANSWER—The cause or causes of vertigo in persons with hypertension is not accurately known. Persons with hypertension with or without cerebral arteriosclerosis may conceivably by sudden motions of the head alter the blood supply to and thereby the hydrodynamics of the endolymph system or the static labyrinth and so produce dizziness. Changes in the walls of the end arteries of the labyrinth may further lead to degenerative alterations in the neuroepithelium of the inner ear and so cause vertigo. Blood vessel changes of this type may also be responsible for occasional and minute hemorrhages into the labyrinth producing thereby abnormal sensations roughly classed as vertiginous.

It is clear that treatment must in large part be empiric and symptomatic. In general therapy should be directed toward the

treatment of the primary ailment and secondarily toward the vertigo. Such latter efforts tend to pattern themselves after the treatment in vogue for Menieres syndrome, although the causation of the latter and the history and findings are thought to be quite different from that seen in persons with hypertension.

The physician may try limitation of fluids for a while, thus water may be restricted to about 1 pint a day. In this country, however, many favor instead a low sodium diet and the ingestion of ammonium chloride as recommended by Furstenberg. The latter is given in capsules, six 7½ grain (0.5 Gm.) capsules being taken three times daily with meals. This is kept up for three days and the drug is then omitted for two days and again resumed. It is best to give the drug in divided doses between mouthfuls of food to avoid gastric distress and vomiting. The treatment is carried on for about six weeks when the ammonium chloride is discontinued, but the salt poor diet is pursued further for another six weeks.

Constipation should be avoided. Excessive use of tobacco and abuse of tea and coffee should be forbidden. Small doses of phenobarbital as well as potassium bromide are occasionally found useful. The sodium salts of these should not be given. If the patient is an older person some thought should be given to the possibility of the presence and the correction of a vitamin lack. The patient should be cautioned about sudden changes in position of the head as in suddenly arising from bed and in leaning forward to wash the face and tie the shoe laces. It is obvious that the treatment recommended is not based on an exact knowledge of the cause of the symptoms and is but a rationalization of the incomplete knowledge of the day.

UNCOOPERATIVE PATIENTS WITH SYPHILIS

To the Editor—In October 1939 a married couple came to me with syphilis in the initial stage. They were put on alternating nearsphenamine 0.6 Gm. and intramuscular bismuth subsalicylate according to the Public Health Service schedule until March 23, 1940 receiving in this time eighteen doses of nearsphenamine and four doses of bismuth each. In March 1940 I became ill but arranged for their treatment with a neighboring physician of their own choice. On returning to work in July 1940 I persuaded them with considerable trouble to resume treatment which I completed in December 1941. They have in that time received thirty-four doses of nearsphenamine and thirty-six doses of bismuth each. In the interval of four months during which I was ill they did not take any treatment as I had arranged for them. Except for those four months they were quite regular in coming in for their treatment. On Jan. 10, 1943 I took a Wassermann test which was positive in the wife as were also the Kline and Kahn reactions. I do not believe that these people will be willing to take extensive treatment again. They have a large family and I should like to give them such treatment as they are willing to take and such as will keep down the infection until the disease gets more advanced. These are the things that I wish to know. What would you suggest as the minimum method of keeping the disease under control? How long will it probably be until these cases can be depended on to be noninfectious without treatment?

MD Iowa

ANSWER—There is no minimum method of keeping syphilis under control. No guess can be expressed as to the length of time in which these patients will remain noninfectious without treatment. The only thing that can be said in this respect is that 85 per cent of infectious relapses occur within the first two years after the cessation of treatment.

The first correct procedure in the management of this situation at the moment is an immediate examination of the spinal fluid in both husband and wife. The enquirer gives no information as to the recent serologic status of the husband although it is implied since the wife is still seropositive that the husband may be seronegative. If the husband shows no physical evidence of syphilis if his blood test is negative now and if the spinal fluid is now normal he does not require further treatment but should be followed with blood tests every two months for the next year every six months thereafter for an indefinite period of time and with annual physical examinations.

The wife certainly requires more treatment. The nature and kind of this cannot be outlined without knowledge as to the spinal fluid findings.

There is no royal road to the cure of syphilis and if the patients refuse to take adequate treatment they should do so at their own risk after the possible consequences have been fully explained. To give an occasional treatment such as they are willing to take and such as will keep down the infection until the disease gets more advanced is medically indefensible.

PLASMA BICARBONATE

To the Editor—What is the normal value for plasma bicarbonate expressed as milliequivalents per liter? If the plasma bicarbonate is directly related to the carbon dioxide combining power, how is it calculated when the value for carbon dioxide combining power is given in volumes per cent?

Joseph H. Davis, Lieutenant, M. C., A. U. S.

ANSWER—The normal range of bicarbonate concentration in plasma of venous blood from the arm is 24 to 31 millimoles per liter (Eyle and Cullen *J. Biol. Chem.* 83:539, 545 [Sept.] 1929). Millimolar concentrations are calculated from volumes per cent of carbon dioxide by the formula

$$\text{Millimoles CO}_2 \text{ per liter} = 0.15 \times \text{volumes per cent CO}_2$$

The total carbon dioxide content was found by Stadie and Van Slyke (*ibid.* 41:191 [Feb.] 1920) to average 94 per cent of the carbon dioxide determined by the method of Van Slyke and Cullen (*ibid.* 30:289 [June] 1917). The bicarbonate content at normal p_{H} is 95 per cent of the total carbon dioxide. Hence the average bicarbonate content is $0.95 \times 0.94 \times$ the CO_2 capacity, or $0.89 \times \text{CO}_2$ capacity.

The factor 0.89 is not constant, it varies between 0.84 and 0.95. Hence calculation of bicarbonate as $0.89 \times \text{CO}_2$ capacity involves a ± 5 per cent error.

For precise gravimetric determination of the bicarbonate concentration of the circulating blood plasma it is necessary to draw the blood without stasis or exposure to air and to centrifuge it without exposure to air. In the plasma thus obtained one then measures both total CO_2 and p_{H} . Bicarbonate is calculated from CO_2 by the equation

$$\text{mM BICO}_3 = \text{mM total CO}_2 \times \frac{1}{1 + 10^{6.1 - p_{\text{H}}}}$$

(Peters and Van Slyke *Quantitative Clinical Chemistry, Interpretations*, p. 881). The value of the factor $\frac{1}{1 + 10^{6.1 - p_{\text{H}}}}$

at different plasma p_{H} values is as follows: p_{H} 7.0, 0.89, 7.1, 0.91, 7.2, 0.93, 7.3, 0.94, 7.4, 0.95, 7.5, 0.96, 7.7, 0.97. Unless the p_{H} is definitely displaced from the normal, one may assume that the p_{H} is 7.4 and calculate simply

$$\text{mM BICO}_3 = 0.95 \times \text{mM total CO}_2$$

A simple method for determining plasma bicarbonate directly by titration is described by Van Slyke, Stillman and Cullen (*J. Biol. Chem.* 38:167 [May] 1919, 52:495 [June] 1922; Peters and Van Slyke *Quantitative Clinical Chemistry, Methods*, p. 822).

SULFONAMIDES AND MOTOR COORDINATION

To the Editor—I have had under my care a number of civilian pilot training boys for streptococcal sore throat, all of them being confined to bed and receiving sulfanilamide in doses of 1 Gm. three times daily. Today there were three airplane accidents all involving possible poor coordination. One of the pilots had not received any sulfanilamide, another had not had any for four days and the other had not had any for seven days. Will you give an opinion regarding the safe period of time before a patient should pilot a plane after having taken this drug?

M. D., Idaho

ANSWER—The effect of sulfanilamide on locomotor coordination persists for approximately forty-eight hours if the drug is given in a full therapeutic dose. Flying personnel who have taken sulfanilamide should therefore be grounded for three days following their last dose of the drug. Owing to the deleterious effects of sulfanilamide on the motor coordination and psychomotor status of the average young adult, the Surgeon Generals of the Army and Navy have ordered that sulfadiazine be used in place of sulfanilamide, since sulfadiazine is as effective therapeutically and has little or no effect on motor coordination. Opinion is somewhat divided as to whether flying personnel should be permitted to fly while taking sulfadiazine. If they are not grounded for other reasons, it is probably safe to permit a flier who is taking sulfadiazine to pilot a plane. This applies also to drivers of motor vehicles.

PSYCHOANALYSIS AND NEUROSIS

To the Editor—On a thorough routine psychoanalysis of the general population without any selection of cases, what percentage could be classed as absolutely free of any trace of neurosis whether active or latent?

M. D., New York

ANSWER—"A thorough routine psychoanalysis of the general population without any selection of cases" has never been carried out and probably never can be carried out. Therefore an answer to this question is not possible.

BILATERAL KIDNEY INFECTION WITH UREA SPLITTING ORGANISMS

To the Editor—I have a urologic patient whose urine reaction I am able to change from alkaline to acid. He has repeated attacks of ureteral colic, bilateral, and has passed several stones. Cystoscopy and x-ray examination reveal no calculi in the kidney, ureter and bladder region at present. The entire bladder is inflamed and covered with white mucus, which is difficult to wash off. The right kidney and bladder specimens are loaded with pus all the time—the left kidney is not quite so bad. Pyelogram and kidney functions approach normal. Culture of urine sediment reveals *B. coli* and *Staphylococci*. I have tried all the sulfonamide compounds and the usual acidifying drugs, mandelic acid and the like, repeated cystoscopies and lavage of kidney pelvis, and I am unable to clear up the infection or render the urine acid. I shall appreciate any suggestions.

H. M. Daniel, M.D., Anderson, S. C.

ANSWER—The patient probably has bilateral kidney infection with a urea splitting organism making for an alkaline urine and tendency toward the production of stone and incrustations. The problem under these conditions of course is a most difficult one and calls for careful persistent management and observation.

With no urinary stasis along the tract from the kidneys through the urethra and without any calcification anywhere in the urinary tract, patients like this respond best to short but thorough courses of sulfathiazole, however, with bladder incrustations these must be treated locally before sulfathiazole management is instituted.

Bladder incrustations are best managed by continuous irrigations, using a two way Foley catheter and rectal drip connection with Albright solution, which consists essentially of citric acid (monohydrate) 32.3, magnesium oxide (anhydrous) 3.8, sodium carbonate (anhydrous) 4.4 and distilled water (to 1,000).

This local acidifier dissolves off incrustations usually in the course of a few days to a week. This local acidifier may be helped by using gluconic acid by mouth and if, this is not available, diluted methylenedichloric acid.

HYPOPROTHROMBINEMIA SECONDARY TO HEPATIC DAMAGE

To the Editor—A woman aged 60 has pain over the right lobe of the liver, ascites, edema of the legs and jaundice of the conjunctiva, also slight skin jaundice. The gallbladder was removed in 1932. Signs and symptoms began about four or five months ago. It has been decided to do an exploratory laparotomy, but the prothrombin test has been 35 to 50 and at present is 40, although we have used everything we know of to increase the blood clotting power during the last three weeks including five blood transfusions. Kindly outline what treatment might bring the prothrombin to a point where operation could be attempted without danger of hemorrhage. Is this probably impossible on account of the bile in the blood? What would be the lowest prothrombin consistent with safety prior to operation?

M. D., Philadelphia

ANSWER—In patients with a hypoprothrombinemia secondary to hepatic damage, administration of vitamin K preparations does not raise the prothrombin level. Blood transfusions will raise the prothrombin temporarily in such cases. Two or three blood transfusions within twenty-four hours before operation should be sufficient to protect the patient against operative hemorrhage. Bile in the blood does not interfere with the formation of prothrombin, as the prothrombin level can be readily raised with vitamin K therapy in patients with uncomplicated obstructive jaundice.

Bleeding does not occur until the prothrombin is reduced to below 20 per cent of normal. Values up to 60 or 70 per cent of normal should allow a fair margin of safety against operative hemorrhage.

PROLONGED USE OF CONDOMS NOT RELATED TO PROSTATITIS

To the Editor—Kindly advise if there are any harmful effects on the prostate from the prolonged use of condoms. Is there any authority on this? What is the opinion of urologists? Several patients have questioned me concerning this. Is there more danger of prostatitis as the patient grows older?

M. D., Illinois

ANSWER—The writer has never seen, heard or read of harmful results occurring to the prostate gland from the prolonged use of condoms. It is difficult to see how this practice could in any way cause prostatitis. Prostatitis is due to infection, either by some distant focus as teeth, tonsils or sinuses, or by influenza, measles, mumps or other diseases or to infection which travels down into the posterior urethra and into the prostate from local infection, like gonorrhea.

SIMILAC

*Similar to
breast milk*

A powdered, modified milk product especially prepared for infant feeding, made from tuberculin tested cow's milk (casein modified) from which part of the butterfat is removed and to which has been added lactose, olive oil, cocoanut oil, corn oil, and cod liver oil concentrate.

Similac provides breast milk proportions of fat, protein, carbohydrate and minerals, in forms that are physically and metabolically suited to the infant's requirements. Similac dependably nourishes -- *from birth until weaning.*

CONTRIBUTORS

EXCLUSIVE PUBLICATION
Articles are accepted for publication on con
dition that they are contributed solely to this
journal

COPYRIGHT Matter appearing in
THE JOURNAL OF THE AMERICAN MEDICAL
ASSOCIATION is covered by copyright. Permis
sion will be granted on request for the repro
duction in reputable publications of anything
in the columns of THE JOURNAL if proper
credit is given. However the reproduction
for commercial purposes of articles appearing
in THE JOURNAL or in any of the special
journals published by the Association will not
be permitted

MANUSCRIPTS Manuscripts should
be typewritten double spaced, and the original,
not the carbon copy submitted. Carbon copies
or single spaced manuscripts will not be con
sidered. Footnotes and bibliographies should
conform to the style of the Quarterly Cumu
lative Index Medicus published by the American
Medical Association. This requires in the order
given name of author, title of article name of
periodical, with volume page month—day of
month if weekly—and year. We cannot promise
to return unused manuscript but try to do so
in every instance. *Used manuscript is not re
turned.* Manuscripts should not be rolled

ILLUSTRATIONS Half tones and
zinc etchings will be furnished by THE JOURNAL
when satisfactory photographs or drawings are
supplied by the author. Each illustration, table,
etc. should bear the author's name on the back.
Photographs should be clear and distinct, draw
ings should be made in black ink on white
paper. Used photographs and drawings are re
turned after the article is published, if re
quested

**ANONYMOUS CONTRI
BUTIONS** whether for publication or infor
mation, or in the way of criticism are con
sidered in the waste basket

NEWS Our readers are requested to
send in items of news also mailed copies of
newspapers containing matters of interest to
physicians. We shall be glad to know the name
of the sender in every instance

PRICE LIST

A price list describing the various publica
tions of the Association will be sent on request

"THE PROOF

of the pudding"

During the past year Franck Chicory has
made thousands of new friends, due un
doubtedly to testimonials on the sale of
coffee. For this reason it is all the more
gratifying to receive the many voluntary
letters of commendation in which the
phrase "the best cup of coffee we ever
drank" is repeated over and over again

We believe that a product which can con
sistently please so many people will also
please you. To that end we will cheer
fully mail you a package of 10 tablets
for the small sum of 10c. Unless you
prefer an unusually stout heverage each
tablet will equal a heaping tablespoon of
dry coffee

Classified Advertisements

Advertisements under the following headings,
\$4 40 for 35 words or less, additional words 11c
each. Key number counted as four words
(Payable in advance) This rate applies for
each insertion

WANTED	Partner	Sanitaria
Apprentice	Partnership	Drug Stores
Assistant	Situation	Location for Sanit
Books	FOR SALE	FOR RENT
Intern	Apparatus	EXCHANGE
Location	Practice	MISCELLANEOUS
Locum Tenens		

KEYED ADVERTISEMENTS—A fee of 25c is
charged to late answers sent care of A M A. Letters
sent in our care are forwarded promptly. RESULTS
are better when an advertisement receives several in
sertions and to those who remit for four consecutive
insertions of a classified advertisement we will give
free two more insertions provided the first four do
not consummate a deal. Notice for free insertions must
be received within two weeks following date of last or
fourth insertion

SEMI-DISPLAY ANNOUNCEMENTS
NOTICE — SHOULD YOU PREFER TO
have your advertisement set in bold type
(Indented like this paragraph) the rate will
be \$5 50 for 35 words additional words
14 cents each

Inquiries About Keyed Advertisements

I frequently we receive requests to this effect
Please send me the address and particulars regard
ing ads No. We are not permitted by adver
tisers who have their mail sent care of A M A to furnish
inquirers information of any kind hence when you
wish to corre
spond with such
an advertiser
address the en
velope in this
manner

In Classified Ads are Payable in Advance To avoid
delay in publishing remit with order

For current issue ad must reach us by 10 a m
Monday

All statements in classified ads are published in good
faith but it is manifestly impossible to make minute
investigation of each advertisement. Physicians not
members of county medical societies should submit
professional references with their advertisement and
thus obviate delay

We exclude from our columns all known questionable
ads and appreciate notification from our readers rela
tive to any misrepresentation. The right is reserved
to reject or modify all advertising copy in conformity
with the rules of the advertising committee

COMMERCIAL ANNOUNCEMENTS

For classified announcements of a commercial
or promotional nature, the rate is \$4 40 for 20
words or less additional words 14 cents each.
This rate is for each insertion. No gratuitous
insertions given (25c extra if keyed through
A M A) This applies to advertisements of firms
or individual in business such as

Placement	Printers	Salesmen
Bureaus	Postgraduate Courses	Insurance
Publishers	Manufacturers	Resorts

In fact anything but personal classified ads

For Semi Display as Above Add 25% Extra

RESULTS VS ECONOMY—DO NOT TRY TO
economize at the expense of the effectiveness of
your advertisement by omitting important and
attractive features. In selling a practice, value
of which runs into hundreds of dollars, it is
surely unwise to run the chance of losing a
prospective purchaser by not including every
important fact and favorable item pertaining
to your proposition. Extra words over thirty-
five cost only 11 cents each

No shadow of slavery or sickness . . .

While men die and others fight on this War for our children may never be more than a game. Medical demands increase and the importance of X-Ray grows. For our children must not only be free, they must have the forces of health and vigor which are so strongly inherent in the Four Freedoms for which we fight.

Though we now know that this weapon of medicine, the X-Ray, may lend itself to such wartime duties as checking for weak spots in the armor plate of a battlewagon or revealing interior flaws in a pressure vessel, let us always uphold the original and most essential job of this medical tool—that of checking the inception and growth of disease.

And we at Patterson are humbly proud to contribute to the work of this science to reaffirm our assurance that intensive screen research is being continued, that the quality and supply of our X-Ray Screens will be maintained.

Behind our army which combats the forces of slavery, we shall continue our fight against the more formidable forces of sickness.

THE PATTERSON SCREEN COMPANY, TOWANDA, PA., U. S. A.

Tonics and Sedatives

FROM THE DOCTOR'S PRACTICE
Sir A patient of mine today told me of some high class biliary surgery that she had performed some seven years ago—in these words:

"He removed some tubes from my bile to my liver and built a casing around my gallbladder."

R. A. K., New York

WHAT A PROBLEM!

Letter received by a Health Column

Dr. I enclose a stamped self-addressed envelope for your answer to my question. It is probably the oddest you've come across, but means a lot to me. The situation is—due to my husband's thrashing around at night, we got a double-decker bed, as I'm pregnant seven months, so he couldn't hurt me, as I've had a miscarriage and am carrying this child along with a cyst. Had to have shots and am taking "E" pills. Well, he slept up on top and me on the bottom. Then he said it was too hot up there and with me protesting, cut the legs off the bottom half—which left him a good 6 inches lower—but me literally "on the floor"—there being only the side frame, the springs, mattress, and then me—just 6 inches off the floor. To get in bed I had to roll in and to get out I had to roll out on the floor to my knees and get up from there. Very difficult as I'm kind of heavy now. I'm very rheumatic too so this bed business is terrific. There is a cold wood-sided basement where the wind whistles all the time, and as we are on the first floor, the floor is awful cold, and the drafts are awful. What I want to know is in my condition is it healthy for me to continue to sleep on the floor? I did one night and due to imagination or other peoples "he put you on the floor?" in horrified tones (even his folks were agast!) I had a miserable night—so I had a big fight with him—said he was inconsiderate, etc., and since have been crawling up the ladder to the 2nd bunk. Now that is some job, especially when I have to get up 1 or 2 times a night. He claims this climbing is harder on me than sleeping on the floor. Could you help? Tell me what to do. The bed can't be fixed. We have no room to put them up as single beds. Should I sleep on our couch, floor, or upper deck? Is it unhealthy so low to the floor? Answer soon as I seem to bawl everytime I look at the bed. We are both unhappy and miserable over it. Please answer.

Let's Go!

...AND HEREIN LIES THE FUTURE OF HEART TESTING

BYOND the war's dark horizon lies a bright new world wherein a marvelous science now aiding us in victory will open the door to an era of undreamed of wonders and developments. Such is the science of electronics providing for man the auxiliaries to do things in a better way, and often to accomplish the "impossible."

In electrocardiography, many improvements and developments we already know were made possible by applications of the electronic tube.

the ultra-portable, simple to use, yet accurate cardiograph instrument of today instantly visible electrocardiograms continuously recorded cardiograms accurate small animal cardiograms electronically amplified auscultation without distortion practical recording of heart sounds simultaneously with one or more electrocardiograms or with cardiogram and sphygmogram.

To all these accomplishments Sanborn electronic engineers have made substantial contributions. Today these men and others in this field are devoting their skill and knowledge to the urgent task of maintaining the survival of all that has gone before—and, keeping pace with war's furious demands, are developing stronger, sturdier, more dependable and still more versatile electronic instruments for the armed forces.

This background of successful electronic application and increased knowledge of electronic possibilities through research and development spells a bright future for the science of heart testing. Medicine has but to state what needs to be done, and—in all probability—the electronic tube will do it.

PSYCHIATRY IN A NUTSHELL (CONT.)—III

RALPH M. LUNAKHOUSER, M.D.
D. THE MANIC

When you find a poor man who is very confused

Who keeps talking as fast as greased lightning

Who keeps moving about and can never be still,

Whose actions and manners are frightening,

Who is losing much weight and does not care to eat,

Who is fearful and in a great panic,

You may be rather sure he's been that way before.

His behavior is typically manic.

In a few weeks or months he'll not be so disturbed.

He will sit all alone and dejected,

Never saying a word, simply dazed and confused.

As though by the whole world neglected.

He still is a manic, in different phase,

With many a fear and obsession.

His poor head is filled with abnormal ideas.

He is now in a state of depression.

Remember the manic—he's up or he's down.

The first stage we call agitation.

And then before long we shall see him depressed.

As though in some deep meditation.

The manic is second in all of the lists.

Of those who have any psychosis,

And, if we remember the up and down phase,

We can usually make diagnosis.

(To be continued)

FROM THE DOCTOR'S PRACTICE

She —Having gotten out a few laughs out of the Times and Boosts column I report these two instances of fun, obtained in the course of pre-employment examinations here.

A man came in holding the unsmoked end of a cigar in his fingers. He was told to enter a cubicle and undress. When ready, the doctor entered, to find him still clutching his cigar. "Put your butt on that window-sill," the doctor said. The man looked at him with some bewilderment, took a chair, and tried to climb up.

A pert but sedate miss was examined. She was asked if she used any alcoholic beverages. "No," she replied. "Do you use tobacco in any form?" "No," she replied. The doctor, amused by the tremble in her eyes, said, "You are a good little girl, aren't you?" "Date me and see," she demurely replied.

REFLECTIONS OF AN ARMY OFFICER ON MEDICAL STUDENTS AND THE WAR

BRIGADIER GENERAL HUGH JACKSON MORGAN
MEDICAL CORPS, UNITED STATES ARMY

My reflections as an officer in the Medical Department of the United States Army are neither carefully arranged nor very clearly expressed. They are based on no grand historical view of the times in which we live nor do they stem from any ordered, philosophical concept of our destiny as human beings on this globe. Moreover, they are directed not to those of my generation but to the medical students and house officers who are in attendance on this occasion. I am especially anxious to make the latter point clear, since I feel that I may be a little closer to the students than to their elders, for it has been my good fortune to have spent a large part of the past eighteen years with medical students. I think I know medical students and I doubt not that a good many of them know me—perhaps better than I know myself. However this may be, I can at least speak frankly and directly with them, and I think they can with me.

Although the timing of an educational experience in medicine is difficult to designate, for our purposes we will agree that the individual concerned is a student during that period of his career which is given over to preparation for his ultimate position in society as a practitioner, teacher or researcher in medicine. This begins at the first year of college and ends with the completion of postgraduate training. Before the completion of his internship the student frequently determines his ultimate goal and can, in his mind's eye, visualize himself in the future as far as professional activities are concerned. Moreover, he has some concept of the environment in which he plans to carry on his professional work. Indeed the majority of medical students have some sort of ordered concept of this future long before they receive their degrees. It is likely that few professions are so conducive to thoughtful long-time planning as medicine. To become a medical student nowadays the premedical curriculum must have been pointed carefully to acceptance by the medical school. Competition begins the day of college matriculation and steadily increases as the months go by. Then comes the inevitable day when the first screening process is instituted—probably most of you remember it. You were successful in passing through several progressively selective preprofessional school screenings and you found yourselves at long last in the medical school of your selection and, equally impor-

tant, in a school which selected you. This was the earliest of many similar screening experiences. In the medical school, competition increased. Academic morbidity was great during the first school year and mortality may have occurred within a few months. It almost always occurs for a few by the end of the first or second year. By graduation time, competition becomes a fixed habit with you. The award of internships is based on medical school performance, assistant residencies on internship performance, residencies on assistant residency performance. Thus quality of current work determines future hospital and medical faculty appointments. Specialization is decided on for those aspiring to the higher echelons of practice, and jockeying for position begins for the long steeplechase ending in certification as a fully qualified specialist. Specialization implies practice and practice implies patients, and patients are usually won—not inherited. Thus, becoming established in practice has its competitive implications too, although we try hard to protect our profession and our patients from the abuses, indignities and commercialism commonly associated with the term, to the end that this competition may be one for quality and opportunity for service rather than for material gain.

I have emphasized the competitive aspects of the activities of the undergraduate and graduate student and practitioner because I feel that because of this competition and other factors which I shall not enumerate there are few disciplines so conducive to the creation of a "one man show." Individualism, independence, objectivity and resourcefulness are engendered by this discipline. The young medical man early in his educational life, knows where he is going and is on his way. Competition successfully met strengthens his determination to attain his objective, and sacrifices to this end become almost reflex. The successful medical student is a marked man among individuals of his age group. He is, relatively speaking a specialist already. He deliberately bypasses or excludes many aspects of life which would attract him were he otherwise engaged. His normal social, economic and oft-times biologic inclinations are deliberately adjusted to consistency with his objective. He practices effectively a kind of isolationism. Celibacy and poverty are his accustomed states, and except for rare understandable, though often lurid lapses, he leaves to his less occupied fellows active participation in the life of the nonmedical world about him.

TWO WORLD WARS

The third and fourth year medical students and some of the younger doctors before me tonight were either nonexistent or were enjoying the security of embryonic or fetal existence or infancy when the first phase of the current war was terminated in the armistice of 1918. Military victory was attained then and according to my way of thinking, forfeited later when our country measured the failure of the League of Nations

The Roger Sylvester Morris Memorial Lecture read before the University of Cincinnati College of Medicine Cincinnati Jan 8 1943 in honor of the late Roger S. Morris formerly professor of medicine and director of the Department of Internal Medicine

by separating itself from its responsibilities and obligations. During the ensuing twenty-four years our country remained an isolated unit in a closely integrated world—a world according to Vice President Wallace, which has become actually smaller when measured by travel time than was our little country at the time our constitution was adopted in 1787. (It is well to remember that this constitution was necessary for the protection of the several states which were no longer isolated enough to feel secure from one another or the rest of the world as individual units.) We worked for peace following World War I, but with no success. Shortly after the armistice of 1918 we repudiated our 1917-1918 slogan to "Make the World Safe for Democracy"—a slogan ridiculed and discarded as we became cynical, 'realistic' 'debunked.' We became quite sophisticated and poked fun at those who still cherished this fine ideal for which men had given their lives. "Anyway," we said, 'it should have been worded 'to make Europe safe for democracy' for who really questioned the safety of democracy in the United States—thousands of miles from Europe and its recurring wars? But in 1941 we rediscovered that the slogan was both realistic and practical, for we learned then that our isolation was no protection and that only by making the world safe for democracy could our American democracy be preserved. It has been demonstrated conclusively in the past decade that there is no safety for any democracy unless there is safety for all.

It appears that in international affairs a gangster or kidnaper makes his decisions as to his next "take" on the same basis that our underworld gangsters and kidnapers operate. Can he get away with it? The gangster is everybody's business because everybody is vulnerable to the gangster at one time or another. To tolerate him and his attack on others only because we think we are strong enough to overcome him should he elect to attack us is putting a very high stake on our judgment. Not only is this dangerous as far as our selfish interests are concerned, but it is also in complete disregard of the responsibility that is part of civilized, enlightened citizenship. The unopposed rape of Manchuria by the Japanese when you were 14 years old, of Abyssinia by the Italians when you were 18 and embarked on your professional career, of Spain by Hitler and Mussolini when you were 19, of China by Japan when you were 20, all gave emphasis to the indifferent, selfish attitude of our democracies. The free people of the world saw fit to allow these things to happen—things which were contrary to their interpretation of right and wrong and in total violation of any concept of international justice and decency. But, at the time they occurred, these outrages did not seem to affect our immediate self interest directly. Indeed, the notion of avoiding violence in our attitude toward them was so strong as to make conspiracy and compromise acceptable to the end that we might have "no war in our time." You were well on in your highly specialized, competitive and absorbing medical education then—and most of you gave little more than enough thought to these developments to decide, along with the majority of your elders, that you wanted to keep your skirts clean of them. You asked only that you be allowed to follow the well defined course of medical progression ahead of you. This had been, was and, you believed, always would be your objective. Others, older and less occupied than you, were of the same detached, indifferent state of mind regarding the conflict, according to the Gallup polls. The European

war was Europe's concern chiefly, and less than 10 per cent of us felt that we should declare war on Germany, although, if there is any comfort in recalling it now, a much larger group was willing to help England even at risk of war. It was not until after the Germans and Italians had overwhelmed Greece in April 1941 that as many as 30 per cent of us felt we should fight the aggressors although even then another 30 per cent of us were opposed to incurring the risk of war by helping England. In October 1941 only 25 per cent of us felt that we should enter the conflict. Is it surprising that medical students and young doctors shared this feeling of indifference and apathy? There was an extremely full life—a life which in peacetimes precluded distractions of any sort and demanded relentless concentration on the single objective of a medical education. Lend-lease and armed neutrality and selective service became topics of serious discussion but were not necessarily definitive distractions, and your major reaction to the ominous developments in the outside world was to hold hard to your course and your goal. Many of you in early 1941 belonged to the 50 to 65 per cent who believed, regardless of the right or wrong of it, that this country would get into the war eventually. Many of you resented this, correctly believing that it was a problem not of your making. It may have held, doubtless did hold a strange, detached fascination for you, but you could put it out of mind whenever the papers and radio would allow and, with the aid of draft board deferment of medical students, you kept at your absorbing task.

OUR ENTRY INTO THE WAR

Then came Dec 7, 1941 and the attack by Japan at Pearl Harbor. Three days later Germany and Italy declared war on us. Whether we liked it or not, and regardless of our previous opinions about the war, it now became our war. Our enemies dispelled confusion and doubt and clarified our position. Germany, Italy and Japan announced that their objectives were to destroy our freedom, enslave us and possess our material assets. The United States was in the war on the side it had favored from the beginning, no longer giving only lip service to idealism and against the dictum that "Might is Right" but also fighting to survive as a free nation in the world. This was a little more than one year ago, and it really came as a shock and dislocation to you, for you had no choice except to relate yourselves to it. Here was something which had actually happened, and it was bigger than your career or anything else. What was your reaction? You know far better than I, but I hazard a guess that it was not altogether that of men impatient and eager for the fray. "The Japs have to be whipped, and the Germans and Italians too—but why should this happen to us?" Certainly you had a right to ask that question. Some of you were not even born when the real answer to your query was laid down. You have had little, if anything, to do with the setting up of this war. My generation is responsible, not yours. Yet on your shoulders must fall the responsibility of correcting the oldsters' mistakes, and life is always like this. My generation and the generation before me had a chance to make the world safe for democracy and we failed. Your generation and mine again will have that chance after this war is won, and it is comforting to believe, as I do, that we shall not fail unless you look to my generation (which, remember, failed once) rather than to your own for leadership. But the war isn't won yet, and if we are to survive at all it must be won. Then will

come the problem of an enduring peace. So let us concern ourselves with the present now and ask of medical students and recent medical graduates: Where do you find yourselves now, today, with relation to the war and your careers?

It appears now that you will very soon find yourselves on active duty in the Army or Navy of the United States—no longer a free agent to follow the line of your ambition and, regardless of all else, to meet competition and bend circumstance to the attainment of the objective which for many of you is as old as your mature life. You are called on at long last, and in no uncertain terms, to compromise with personal ambition and objective. An interference stronger than any you have ever encountered, has developed in your struggle toward your goal and this interference is your loyalty as an American citizen. What is your chief objective now? It is the common objective of all loyal Americans—to bend every effort and utilize every talent to help win the war and thus preserve our country, and then to insure an enduring peace. Is this objective incompatible with your former, prewar objective which was in general to become a doctor of medicine? In the broader sense it is not, for you are more useful to your country now as doctors and potential doctors than you could be as combat soldiers. In this you are more fortunate than your brethren in most of the other walks of life. The war will not prevent the completion of your formal medical education. What about training for a specialty in medicine? This is an important question to those of you who have decided to restrict your work to one field. As far as specialization is concerned it is obvious that it will be possible for but few, if any of you to have two three or four years of postgraduate training before your assignment to duty with the armed forces. Indeed, it is even conceivable that the need for young medical officers in the armed forces might become so great as to preclude the one year of internship now prescribed.

How will the Army use you when you become commissioned in the Medical Corps? I will, first, answer this question the way I believe most of you would answer it. "If I am very very lucky I will be assigned to a general hospital and to the specialty in which I am interested, or if I am lucky I will be assigned to a station hospital or an evacuation or field hospital where professional work has at least some resemblance to that with which I am familiar in civilian life. If I am unlucky I will be assigned to troops where little of my knowledge will be utilized and where I shall acquire no useful professional training."

Regarding the relative importance of assignments in the Medical Department I have a definite opinion. During the past year I have had an opportunity to observe the professional work of our army general and station hospitals in this country. The quality of professional care which is provided is in the main good. The experience and training afforded by the professional services of such hospitals for the junior members of the staff varies in relation to the senior officers of course. In hospitals in which the professional services are headed by men interested in the training of young men general medicine and surgery and the medical and surgical specialties are practiced along conventional lines. The ward officer does the work of the civil hospital intern and assistant resident under the supervision of his section chief. The section chief is responsible to the chief of service medical or surgical as the case may be, and the chiefs of service are respon-

sible to the commanding officer. Ward rounds are held daily in each section, and "grand rounds" bring together all the sections once a week or more. Inter-service consultations, staff meetings, clinical-pathologic conferences and journal clubs complete the program of professional activity with one exception. The recommendations of the ward officer and section chief regarding the final disposition of patients are always reviewed formally by boards composed of representatives of the services and the commanding officer. So much for the professional work of the hospitals. It isn't materially different from practice in our better civilian institutions.

THE FIELD MEDICAL OFFICER

Let us examine the future activities of the "unlucky" majority of you who will be ordered to field duty. The clinical material reaching army hospitals comes to it almost exclusively through the activities of the medical officers who are assigned to troops. Thus the initiation of medical care begins with this medical officer. It is he who decides whether treatment can be provided locally or whether hospitalization is required. His acumen determines whether or not diphtheria, meningitis, pneumonia and measles are promptly recognized, isolated and evacuated for hospital care. Thus triage, or the selection and classification of significant illness and injury, and evacuation are extremely important functions. They are initiated and can be initiated only by the medical officer with troops. It is obvious that the proper functioning of the enormous medical organization which is behind the fighting force is dependent on the skilful, prompt execution of triage and evacuation. In the theaters of operations these functions are conspicuously important, and here as in the training area, the wounded man is dependent on his medical officer also for first aid and emergency treatment. How to prevent death from asphyxia in this sucking chest wound, what to do and how to do it under the existing circumstances for shock, how to handle burns in order to preserve life and the function of the burned part, what to do about simple and compound fractures in order to save life and limb, how to practice hemostasis, how to recognize malingers and the hysterical and how to handle them, which cases to evacuate when facilities are limited and which to retain, which patients to treat when almost overwhelmed by the volume of work, and which to abandon as hopeless, what to do about head wounds and abdominal wounds, how and when to prescribe the sulfonamides for battle casualties and, equally important, how to see that they are available and actually administered, when and how to use tourniquets and when and how not to, how to collect the wounded, transport them to aid stations and further on to definitive treatment, how to control in the most effective way omnipresent pain, how to sustain courage in self and fellows when it is ebbing? The mere asking of these questions indicates a convincingly negative answer to the next. Is there any place in this army where medical knowledge and skill, resourcefulness and courage are more important than in an active first aid station in a battle area?

The health of the fighting men (and these are the only men who will gain us the victory) is in the hands of the field medical officer. He is the family doctor during the training period and he accompanies his clientele into combat. His knowledge of camp sanitation safeguards their health. Preventive medicine in its most exciting, productive aspects is his interest and

duty. He is a practical specialist in hygiene and sanitation. He is, in one man, sanitarian, diagnostician, expert in traumatic surgery with all its complications, expert in triage, expert in evacuation, morale officer. And in order to accomplish his mission, he also must know something about map reading, logistics and military tactics.

I have been describing a doctor who is foreign to civil concepts of medical practice—a specialist who is recognized only by the military. Just now the exigencies of life are such that, for the winning of this war, he is the most important doctor extant. And the winning of the war is for the time being all that counts. Each one of us here would be carrying a gun were it not for the fact that we can actually help win the war more effectively by being a doctor or training to be one. Although ours is a noncombatant service I am sure we take no pride in that classification of our function when there is so much at stake and when combat alone will settle the issue. If we weren't contributing more toward the victory by being in this noncombatant medical department than we could by taking up guns, then we would get to the guns for otherwise, when men are fighting to preserve our lives and institutions our position would be intolerable.

The doctors of our country during past wars created a great tradition. I predict that this tradition will be not only sustained but also enriched by the present generation of medical men. During this war you will be guided in your roles by the example provided you by the distinguished physician whose memory we honor this evening. In this assurance I shall conclude these remarks by reading to you a few paragraphs by another distinguished physician. They were written at the outbreak of the war between the states, sixteen years before Dr. Morris was born. In 1861 Dr. Oliver Wendell Holmes, in his fifty-second year and Parkman professor of anatomy and physiology at Harvard University, terminated an introductory lecture to medical students as follows:

"It is time to bring these crowded remarks to a close. The day has been when at the beginning of a course of lectures I should have thought it fitting to exhort you to diligence and entire devotion to your tasks as students. It is not so now. The young man who has not heard the clarion voices of honor and of duty now sounding throughout the land will heed no word of mine. In the camp or the city, in the field or the hospital, under sheltering roof or half protecting canvas or open sky, shedding our own blood or standing that of our wounded defenders, students or teachers—whatever our calling and our ability—we belong not to ourselves, but to our imperiled country, whose danger is our calamity, whose ruin would be our enslavement, whose rescue shall be our earthly salvation."

"You cannot all follow the armies of your country to the field, but remember that he who labors for the general good at home is an ununiformed soldier in the same holy cause with those who bear arms or minister at the side of the ambulance and in the camp hospital."

With these stirring words and, with a salute from my Chief, Surgeon General James C. Magee, to the ununiformed soldiers who constitute the faculties and students of the medical schools, to the staffs of civilian hospitals, to the essential practitioners in rural and urban communities, to civilian doctors all who are carrying their share of the heavy load imposed by our country's total war effort, I conclude the Roger Sylvester Morris Memorial Lecture for 1942-1943.

ANORECTAL LYMPHOGRANULOMA VENEREUM

ARTHUR W. GRACE, M.D.

Professor of Dermatology and Syphilology,
Long Island College of Medicine

BROOKLYN

I have studied lymphogranuloma venereum at the New York Hospital since 1932, largely in a clinic specially devoted to the disease. During that period Frei tests were performed on all inpatients and outpatients who presented symptoms or signs which were at the time regarded as lymphogranulomatous. The attendance of patients at the Lymphogranuloma Clinic was regular and extended, in most instances, over a period of years. The progress of clinical manifestations was closely followed by repeated proctoscopic and gynecologic examinations. From 1932 through 1937, treatment consisted chiefly of injections of antimony and potassium tartrate, fuadin, neostam and Frei antigen (by the intradermal and subcutaneous routes). As these remedies were virtually ineffective, the progress of the disease in the persons so treated must have differed little from that in untreated persons. Since 1938 therapy has been carried out mainly with the sulfonamide compounds, principally sulfathiazole and sulfamylamide.

Early in this study¹ it was recognized that of all the clinical manifestations of lymphogranuloma venereum those which involve the anorectal region are the most important, accordingly, all information was carefully gathered which might throw light on the genesis and progress of the disease in this area of the body. The prime significance of the anorectal lesions rests on the following facts:

They may be, and frequently are, of great chronicity, they are infectious during the period of their activity, they are not completely controlled by any form of therapy, they may not become apparent until great structural change has occurred in the bowel wall, they may lead to complete closure of the bowel, to considerable local deformity and, in rare instances, to death.

Among the unanswered questions of anorectal lymphogranuloma are the frequency of occurrence of the symptomatic and asymptomatic disease in the community, the relative distribution of the entities which comprise the condition, the progress of certain of the commoner entities after their inception, the relation of the anorectal disease to inguinal lymphadenopathy and, vice versa, the mode of acquisition and the status of present therapeutic methods. This paper is an attempt to answer these questions.

THE ESTIMATED FREQUENCY OF OCCURRENCE OF LYMPHOGRANULOMA VENEREUM IN NEW YORK CITY

There has been an increase in the number of cases of symptomatic lymphogranuloma discovered annually at the New York Hospital during the past nine years. The sharp rise which occurred in 1934 and again in

Emmerich, and Lichtenstein, L. Virus of Lymphogranuloma Inguinale,
Am J Path 11: 827 (Sept) 1935.

1940 accompanied the introduction of mouse brain² and yolk sac³ antigens respectively. The unlimited supply of the former material enabled many more tests to be performed than were possible with the small stocks of human antigen then available and the greater sensitivity of the yolk sac material (also available in unlimited quantity) led to the discovery of reactors more weakly positive than could be detected by the use of mouse brain antigen. The smaller rise in 1941 followed the introduction, in that year of routine Frei tests in all cases of chronic cystitis. It is not possible therefore, to state whether or not an actual increase in frequency of the symptomatic disease has occurred in New York City since 1933.

The data of the accompanying table show that symptomatic lymphogranuloma venereum is now found in approximately 1 of every 1,000 persons admitted to the New York Hospital. It is likely that a higher incidence of the disease would have been observed had all, instead of only 10 per cent, of 600 cases of fistula in ano and perirectal abscess been Frei tested. The clientele of the hospital can be regarded as a cross section of the city's population, although the institution is situated in a predominantly white district. Proportionately, therefore about 7,000 cases of symptomatic lymphogranuloma must occur annually among the 7,000,000 inhabitants of New York City. Asymptomatic lymphogranuloma venereum occurs much more frequently than the symptomatic form and is most commonly observed among those who have other venereal diseases.⁴ Thus 42.1 per cent of the syphilitic patients at the New York Hospital were found to have asymptomatic lymphogranuloma. Disregarding a comparatively small number of cases of gonorrhea, in which the incidence of asymptomatic lymphogranuloma is probably comparable to that in syphilis, there were, at the New York Hospital between 1936 and 1941, approximately 9 cases of asymptomatic to 1 of symptomatic lymphogranuloma venereum.

THE RELATIVE DISTRIBUTION OF THE CLINICAL MANIFESTATIONS OF LYMPHOGRANULOMA VENEREUM

Two hundred and seventy-six patients showed 348 clinical manifestations of lymphogranuloma venereum. The regions most frequently affected with the disease are, in descending order of frequency, the anorectal space, the inguinal region, the genital region and the lower urinary tract, more than half of the cases present anorectal manifestations, the commonest of which are proctitis, with or without stricture, fistula in ano and perirectal abscess. The proportion of white patients and of the male sex who suffer from anorectal lymphogranuloma is higher than has been generally believed. Finer analysis of the material reveals that 48.7 per cent of such lesions occurred in white males, 13.5 per cent in white females and 29.5 per cent in Negro females. Only one third of the males were known to be homosexuals, all of whom adopted the passive role

CONSIDERATION OF CERTAIN OF THE COMMONER ENTITIES OF ANORECTAL LYMPHOGRANULOMA VENEREUM

Studies of the development of proctitis in male homosexuals indicate that an average period of six weeks elapses between infection of the anorectal mucosa and the appearance of symptoms. The commonest early sign of lymphogranulomatous involvement of the anorectal mucosa is the passage of blood by the anus. This is a direct consequence of the replacement of a portion of the mucosa by granulation tissue resulting from the local action of the virus. Bacterial infection of the raw surface together with the pyogenic property of the virus soon causes the anal discharge to be purulent. Contraction of the fibrous elements of the granulation tissue produces a narrowing of the lumen of the bowel which may be partial (stricture) or complete (stenosis). Infections of the lower portion of the bowel may be discovered before or after narrowing of the lumen has occurred. In the former instance the condition is known as proctitis without stricture and, in the latter, as proctitis with stricture. The invasive properties of

Annual Number of New Cases of Symptomatic Lymphogranuloma Venereum per Ten Thousand Inpatients and Outpatients, New York Hospital 1933-1941

Year	Number of New Cases of Symptomatic Lymphogranuloma Venereum	Total Number of New Admissions	Cases of Symptomatic Lymphogranuloma Venereum per 10,000 Admissions
1933	10	40,574	2.4
1934	26	47,419	6.0
1935	27	41,123	6.1
1936	32	45,977	7.0
1937	33	44,484	7.4
1938	25	43,411	8.1
1939	30	41,505	7.1
1940	39	41,829	9.3
1941	44	49,041	10.5

the virus deposited either perianally or within the bowel lumen lead also to the formation of fistula in ano and perirectal abscess which may precede, succeed or be unassociated with the development of proctitis with or without stricture.

Proctitis Without Stricture—Seven eighths of the patients with proctitis without stricture had no antecedent history of anorectal disease. The remainder had had perirectal abscess or fistula in ano at an average interval of 1.7 years. The proportion of patients with proctitis without stricture which subsequently become strictured is not exactly known but is probably in the neighborhood of one third, 15 of our series of 44 had stricture at an average interval of 10.9 months after the appearance of the proctitis. It would seem also that unless stricture develops within three years after the onset of anorectal inflammation a condition of chronic proctitis without stricture will result. Twelve such cases were observed in which the average duration of the proctitis was eight years with limits of three and eighteen years respectively. In only 1 case was lymphogranulomatous proctitis observed to heal spontaneously.

Proctitis without stricture is predominantly found in men who constituted 81.8 per cent of the series. Such male preponderance is due, I believe, to the fact that approximately three fourths of the men were homosexuals who adopted the passive role and whose anorectal mucosa therefore received a concentration of the

virus sufficiently heavy to produce the characteristic changes simultaneously over relatively large areas of the bowel. In the female, virus usually deposited in the vagina and on the external genitalia, reaches the anorectal mucosa through contiguous moist surfaces more slowly, and probably in lower concentrations, than in the male homosexual. The acute phase of the infection accordingly, is less apt to occur in women, and considerable structural changes are often found to have taken place in the female anorectal mucosa and bowel wall by the time the condition reveals itself through the appearance of a bloody, purulent, anal discharge. Proctitis without stricture is largely a manifestation of lymphogranuloma venereum. Forty-four patients or 84.6 per cent, gave a positive and 8 patients a negative Frei reaction. It is interesting to note that, in 7 of the cases presenting negative reactions the proctitis healed spontaneously within an average period of twenty-two months, with limits of three and fifty-two months respectively.

Proctitis With Stricture—This condition differs from proctitis without stricture chiefly in the possession in the bowel wall, of a firm band of fibrous tissue which encircles and narrows the lumen. The degree of closure of the bowel varies from being just perceptible to being complete. The fibrous band, or stricture, is usually single may extend over several inches of the wall and occurs most frequently within reach of the examining finger. The condition is not acute but is of considerable chronicity and is accompanied by a bloody, purulent anal discharge. In the absence of anal fissure there is little pain. The smallest diameter of the lumen of the bowel compatible with evacuation, aided by cathartics, was approximately 8 mm. The number of cases of proctitis with stricture in which colostomy was required for relief of symptoms of obstruction was relatively small 17, or 18.9 per cent, of our series having had to submit to this operation, three fourths of the group were females and the remaining 4 persons were white male homosexuals. The average period that elapsed between the onset of anorectal disease and the performance of colostomy was 7.2 years, with limits of one and twenty-two years respectively.

In one half of the cases of proctitis with stricture there was no history of either previous anorectal disease or sequelae in the anorectal area. Approximately one third began, in descending order of frequency, as proctitis without stricture, fistula in ano, perirectal abscess and perianal abscess. There is evidence to show that proctitis with stricture requires a considerably longer period for its development when preceded by the three last named entities than when it is a sequel of proctitis without stricture. The remaining one sixth of the cases of proctitis with stricture developed, while the proctitis was still active, other anorectal manifestations, of which the commonest were fistula in ano, rectovaginal fistula and perirectal abscess. The distribution by sexes of 90 cases of proctitis with stricture was as follows: males 36.7 per cent, females 63.3 per cent. The preponderance of females is partly due, I believe, to the fact, already mentioned, that males tend more than females to develop chronic proctitis without stricture. Proctitis with stricture is almost exclusively a manifestation of lymphogranuloma venereum. 96.8 per cent of 93 patients yielded a positive Frei reaction.

Stricture Without Proctitis—This term is applied to those cases in which the anorectal mucosa is smooth and without ulceration and the bowel lumen is narrowed

by the presence of a stricture in the form of a diaphragm with a small central aperture. The condition appears inactive and there is no history of an antecedent anal discharge. It is possible that these cases represent the end stage of an inflammatory process which has commenced outside the bowel wall and traveled inward as far as but without involving the mucosa. Stricture without proctitis occurs most commonly in women, who furnished 64.3 per cent of our series of 14 cases, slightly more than one half of the patients gave a positive Frei reaction.

Fistula In Ano—In this condition there is a tract which passes through the perirectal or perianal tissues and connects the bowel lumen with the cutaneous surface usually in the neighborhood of the anus. The patient is made aware of the fistulous tract by the appearance of a perianal discharge. During the period of this study 340 persons with fistula in ano were observed at the New York Hospital, 54 had concomitant perirectal abscess. Frei tests were performed in only 37 cases, of which 19 were positive. It is probable that many cases of lymphogranuloma venereum were overlooked in the untested material.

Perirectal Abscess—Two hundred and fifty-nine persons were diagnosed as presenting perirectal abscess during the course of this study. 54 had concomitant fistula in ano. Frei tests were performed in not more than 26 cases in 12 of which there was a positive reaction. It is likely that many cases of lymphogranuloma venereum were unrecognized in the untested material.

INGUINAL ADENOPATHY IN ASSOCIATION WITH ANORECTAL LYMPHOGRANULOMA VENEREUM

The development of anorectal lymphogranuloma may be unassociated with preceded accompanied or followed by the occurrence of inguinal adenopathy. It is my belief that such adenopathy is a direct consequence of the presence of the virus in the perineal perianal and anal areas whose lymph channels drain directly into the inguinal nodes. The majority of patients do not show inguinal involvement at any time. 59.7 per cent of our series of 164 persons falling into this category. The adenopathy which developed in each of the remaining three groups was unilateral and suppurative in approximately 70 per cent of 66 persons. In no instance were the nodes or pus examined for the presence of the lymphogranuloma virus. Pus was studied bacteriologically, however in 3 cases 1 in which the adenopathy was concomitant with and 2 in which it followed the development of anorectal disease at an interval of six months and ten years respectively, no organisms were found.

Inguinal Adenopathy Preceding Anorectal Lymphogranuloma—This the commonest time relation, included 31 persons, or 18.9 per cent of the series. The group consisted of approximately equal numbers of males and females, both of whom showed an average interval of ten years between development of adenopathy and of anorectal manifestations. About one half of the cases were observed for a period of five years or less. Rectal examination was not made in any person during the existence of the adenopathy. When first observed two thirds of the patients had proctitis with stricture, and the remainder proctitis without stricture or fistula in ano.

Inguinal Adenopathy Concomitant with Anorectal Lymphogranuloma—The group comprised 14 males and 7 females, or 12.9 per cent of the series. The

exact nature of the anorectal condition was known in 13 instances among which proctitis without stricture fistula in ano and perirectal abscess were almost equally represented. There was only 1 case of proctitis with stricture.

Inguinal Adenopathy Following Anorectal Lymphogranuloma—There were 8 men and 6 women in this category, which made up 8.5 per cent of the series. The average interval between the development of anorectal disease and inguinal adenopathy was 8.8 and 4.9 years for men and women respectively. Ten persons had proctitis with stricture and 3 all males proctitis without stricture.

LYMPHOGRANULOMATOUS INGUINAL ADENOPATHY UNASSOCIATED WITH ANORECTAL LYMPHO- GRANULOMA VENEREUM

Sixty-seven males and 10 females with inguinal adenopathy or with scars from earlier suppurative lesions in the groin, gave positive Frei reactions. There was neither history nor evidence in the group of other clinical manifestations which could be regarded as lymphogranulomatous. Primary lesions were present on the external genitalia in 15 persons (1 female). In approximately three fourths of the cases the adenopathy was unilateral and suppurative. The average period of observation of the group since the development of adenopathy was 7.8 years with one half of the cases being studied for five years or less. Proctoscopic and gynecologic examinations were made during the existence of the adenopathy and, subsequently, at intervals of approximately three months in order to determine the frequency with which lymphogranulomatous inguinal adenopathy unassociated at its inception with perineal, perianal or anal lesions, was followed by anorectal lymphogranuloma. Considerable importance was attached to this point in view of the widespread but unproved belief that the anorectal disease is a sequel of lymphogranulomatous infection of the inguinal lobes. Not one case of anorectal lymphogranuloma developed in the group. It was therefore concluded that, in the absence of perineal, perianal or anal lesions lymphogranulomatous inguinal adenopathy is seldom if ever followed by the anorectal disease.

THE MODE OF ACQUISITION OF ANORECTAL LYMPHOGRANULOMA VENEREUM

It is my belief that the lesions of anorectal lymphogranuloma arise by deposition of the virus either on the anorectal mucosa or in the perineal or perianal area—in males partly by the practice of pederasty and in females as a result of the contiguity of the vulva and the anus. Evidence in support of this statement is both direct and indirect. The former includes the work of Levaditi, Molhret and Rennie⁵ who in 1935 produced the pathologic changes characteristic of lymphogranuloma venereum in the rectum of chimpanzees by direct inoculation of the virus into the mucosa. The infection of children by the use of an enema tip in common with a lymphogranulomatous person also falls into this category. Indirect evidence is provided by the studies of the Lymphogranuloma Clinic of the New York Hospital and is divided into two groups—certain and 'very probable'. The two groups contain 64.4 per cent of the males and 39 per cent of the females affected with anorectal lymphogranuloma. Included in the cer-

tain" category are 42 males (36 homosexuals) and 7 females in the "very probable," 14 males and 23 females. Primary infection of the mucosa is regarded as certain in all male homosexuals with the anorectal disease and also in those persons of either sex in whom inguinal adenopathy appeared concomitantly with the development of anorectal lymphogranuloma. The largest group in the "very probable" division was composed of 11 males and 14 females in whom inguinal adenopathy unilateral and suppurative in approximately 70 per cent of the cases and unassociated in all with infections in the lower limb had preceded the onset of the anorectal disease by an average period of ten years. Although none of these 25 persons were seen during the existence of the adenopathy, the site of their primary lesions has been placed in the anorectal area in virtue of the fact that none of 77 other persons with lymphogranulomatous inguinal adenopathy, observed for practically the same period as the 25 and with primary lesions either on the external genitalia or not demonstrable at all subsequently had anorectal disease. Included also in the "very probable" category are 3 males and 9 females in whom proctitis with or without stricture followed such conditions as fistula in ano, perirectal abscess, perianal abscess, perianal sinus, anal fissure and granulomatous perianal and vulval masses.

TREATMENT OF ANORECTAL LYMPHOGRANULOMA VENEREUM

It is now well established that the sulfonamide drugs will cause the regression of lymphogranulomatous inguinal adenitis, suppurative and nonsuppurative, within a period of approximately five weeks.⁶ Sulfanilamide the first of these drugs to be employed produced many toxic reactions and has now been replaced by sulfathiazole. The latter drug is administered in a course which consists of 15 Gm three times daily for two weeks followed immediately by 1 Gm three times daily for three weeks. The manifestation of the anorectal disease which is most responsive to sulfonamide therapy is proctitis which, unlike lymphogranulomatous adenitis seldom heals spontaneously. Cases of short duration without stricture can be completely healed. Long-standing cases, and all with stricture, require at least one year's therapy with rest periods of from two to three weeks after each course of treatment. The amount of anal discharge lessens shortly after treatment is begun and ultimately ceases.

Follow-up studies now in progress at the New York Hospital however indicate that the cessation of anal discharge and absence of proctoscopic signs of activity are not always certain evidence of cure of lymphogranulomatous proctitis. Anal discharge and inflammation of the anorectal mucosa have reappeared in a number of cases of apparent cure and have been controlled by resumption of sulfathiazole therapy.

I am now inclined to believe that lymphogranulomatous proctitis should be treated by alternation of a sulfonamide compound and inactivated virus the latter to be administered intravenously and derived from the infected chick embryo. Such chick preparations have furnished a means of obtaining practically pure suspensions of the virus which are so potent that in a dilution of 1 in 750 they will produce a Frei reaction equal in intensity to that given by the best human pus antigens whose physical qualities render them unsuit-

⁵ Levaditi, C., Molhret, L. and Rennie, I. Identité étiologique entre la maladie de Nicolas et l'aire et certaines anrectites ou rectocolites végétantes. Etude expérimentale. Bull. Acad. de med. 1935 113: 439 (April 9) 1935.

able for use in a concentration higher than 1 in 5. If the previous failure of Frei antigen, that is inactivated virus, therapy to benefit more than a small proportion of patients with lymphogranuloma was due to the low concentration of virus in the human or mouse brain preparations employed that difficulty no longer exists and antigen therapy should be reattempted with concentrations of inactivated virus much higher than those hitherto employed.

Surgery has a place in the treatment of many of the manifestations of anorectal lymphogranuloma. It should however be preceded and followed by at least one course of sulfadiazole therapy. Fibrous structure is uninfluenced by any form of treatment, in the absence of proctitis, the lumen of the strictured area may be enlarged by the use of dilators.

525 East Sixth-Fifth Street

TREATMENT OF HYPERTHYROIDISM WITH THIOUREA AND THIOURACIL

E. B. ASTWOOD, M.D.
BOSTON

Two series of chemical compounds have been found to possess the unique property of inhibiting the endocrine function of the thyroid gland. The administration of these agents to experimental animals is followed, after a short latent period, by a lowering of the basal oxygen consumption, a decrease in the rate of growth and development and a diminished food intake—changes which are consistent with a state of hypothyroidism. In certain animal species these changes are accompanied by a hyperplasia of the thyroid gland which is apparently compensatory in nature and mediated by the anterior lobe of the pituitary. It was the object of this investigation to determine whether the endocrine function of the human thyroid gland could be inhibited by these compounds and to obtain information concerning their dosage and toxicity in individuals with normal thyroid glands and in cases of hyperthyroidism.

It was first pointed out by the Mackenzies and McCollum¹ that sulfaguanidine would induce thyroid hyperplasia in rats, an effect not influenced by adding iodide to the diet but one which could be abolished by the administration of effective doses of thyroxine. Similar thyroid changes were observed in rats by Richter and Chisby² and by Kennedy³ as the result of the administration of thiourea derivatives. Further studies on this phenomenon have demonstrated that the primary action of compounds of these two types is centered on the inhibition of thyroid hormone production.⁴

This work was done under the auspices of the University Committee on Pharmacotherapy.

From the departments of Medicine and Pharmacology, Harvard Medical School, and the medical clinic of the Peter Bent Brigham Hospital.

The thiouracil was supplied by Dr. R. O. Roblin, American Cyanamid Company, Stamford, Conn., and Dr. B. W. Carey of the Lederle Laboratories, Inc., Pearl River, N. Y.

More than one hundred compounds have been tested in order to select highly active substances of low toxicity for clinical use. Most of the derivatives of thiourea exhibited some activity but varied widely in toxicity, thiourea itself being the least toxic of all. 2-Thiouracil was the most highly active compound tested and the minimal lethal dose of this substance in rats was more than 100 times the dose necessary to produce a detectable thyroid effect. 2-Thiouracil, 2-thiobarbituric acid, diethyl thiourea and several derivatives of 2-thiohydantoin were two to five times as active as thiourea but were somewhat more toxic, especially the thiohydantoin.

A second series of active compounds included a number of aniline derivatives such as p-aminobenzoic acid, p-aminophenylacetic acid and related compounds and all of the commonly used sulfonamides. This class of substances, with the exception of the highly active sulfadiazine, was considerably less active than the thioureas.

From a clinical point of view thiourea and thiouracil appeared to be the most promising compounds and were therefore used in studies on normal persons and on patients with hyperthyroidism.

The substances under investigation were administered by mouth in the form of tablets or in capsules. The larger quantities were given in divided doses over each

Doses Administered for Short Periods of Time Without Detectable Toxic Effects and with No Change in the Basal Metabolic Rate

Diagnosis	Compound	Daily Dose, Gm	Duration of Treatment, Days	Total Dose, Gm
Cardiac decompensation	Thiourea	2.0	17	34
Rheumatoid arthritis	Thiourea	2.0	13	26
Diabetes mellitus	Thiouracil	1.0	7	7
Liver (cause unknown)	Thiouracil	0.4	30	12
Carcinoma of the thyroid	Thiouracil	1.0	24	24
Hyperthyroidism	Thiourea	0.5-1.5	5	5
Hyperthyroidism	Thiouracil	0.6-1.0	10	8.4
Hyperthyroidism	Sulfadiazine	5.0-10.0	10	56

twenty-four hours, the smaller in a single dose after the evening meal. Frequent determinations of the basal metabolic rate and serum cholesterol were made.

PRELIMINARY EXPERIMENTS

Data on the first 8 cases studied are shown in the accompanying table. Four persons exhibiting no evidence of hyperthyroidism were treated, 2 received 2 Gm of thiourea daily and 2 received 0.4 and 1.0 Gm of thiouracil, respectively. Treatment was continued for thirteen to thirty days and during this period no change in the basal metabolic rate occurred, the patients exhibited no signs and experienced no symptoms that could be attributed to the drugs.

One patient with advanced cardiac decompensation was treated with 1 Gm of thiouracil daily for twenty-four days. This patient had a large nodular thyroid gland and a metabolic rate of +20 to +30 per cent under conditions which were not basal. No definite lowering of the metabolic rate occurred during treatment and at operation a carcinoma of the thyroid was found. The remainder of the gland was composed of nodules of colloid filled alveoli with uniformly flat epithelium.

5. Astwood, E. B. The Chemical Nature of Compounds Which Inhibit the Function of the Thyroid Gland, *J. Pharmacol. & Exper. Therap.*, to be published.

The first 3 cases of hyperthyroidism were treated for short periods of time during the usual preoperative period of rest in bed. Treatment was continued for five ten and ten days respectively. These experiments were made before it was recognized from studies on animals that a considerable latent period was to be expected before the metabolic rate would fall. The slight decreases in metabolic rate that occurred during these periods were not greater than may have occurred from rest alone. Microscopic examination of the portions of the thyroids removed at operation did not reveal any changes which could with certainty be attributed to the treatment.

Subsequent studies were confined to the administration of thiourea and thiouracil for periods of three weeks or longer to patients with hyperthyroidism. Three cases which have been observed for a sufficiently long period of time are reported.

REPORT OF CASES

CASE 1—A man aged 58, a janitor, entered the hospital because of increasing weakness, progressive weight loss, nocturia, polyuria and dyspnea of one year's duration. Two months prior to admission these symptoms became accentuated and on consultation at another hospital diabetes mellitus was diagnosed and treatment instituted. Fifteen units of protamine zinc insulin daily and a low carbohydrate diet resulted in a partial control of the glycosuria, but there was no symptomatic improvement and the patient entered this hospital for further investigation. Examination revealed a moderate degree of diffuse enlargement of the thyroid gland, a fine tremor of the hands and a warm moist skin. The basal metabolic rate was $+25$ to $+35$ per cent on repeated determinations, the blood cholesterol was 130 mg per hundred cubic centimeters and the glycosuria persisted in spite of an increase in insulin to 40 units daily.

Details of treatment and subsequent course are shown in chart 1. Thiourea was given orally in 0.5 Gm doses twice daily for eight days and four times daily for the next thirteen days. The metabolic rate began to fall on the ninth day of treatment and was normal by the sixteenth day. On the tenth day of treatment hypoglycemic symptoms became frequent and on discontinuation of the insulin the urine sugar remained low never exceeding a trace. One week after the thiourea was discontinued the metabolic rate again became elevated and the glycosuria returned. Resumption of treatment with thiourea was followed by a prompt return of the metabolic rate to normal and a great decrease in the glycosuria. After a period of three weeks at home and one month after the beginning of the second course of thiourea the patient reentered the hospital for study. At this time there was a maculopapular eruption on the face and on the extensor aspects of the extremities similar to that seen in chronic bromide intoxication. The face appeared to be edematous, the basal metabolic rate was -12 per cent and the blood cholesterol was 407 mg per hundred cubic centimeters. The drug was discontinued the rash cleared within four days, the basal metabolic rate rose to a maximum of $+19$ per cent and glycosuria returned. A third course of treatment was begun thiouracil being substituted for the thiourea in a dose of 0.4 Gm daily. After the metabolic rate had fallen and the glycosuria decreased the dosage was decreased to 0.2 Gm daily and the patient returned home. After forty days at home he returned in good condition having regained his normal body weight. The metabolic rate

was -2 per cent, the blood cholesterol was 250 mg per hundred cubic centimeters and there was a trace of sugar in the urine. The thyroid gland was found to be approximately the same size as it had been when treatment was first begun. After he was hospitalized the drug was discontinued. There was a transient and questionably significant elevation of the basal metabolic rate (maximum $+16$ per cent on one reading), and as the urine remained virtually sugar free the patient was discharged home without treatment. He obtained employment as a locomotive engineer and was able to carry heavy duties for a period of two months. However, weakness gradually returned and with this he noted nervousness, dyspnea, palpitation and pronounced weight loss. When he was hospitalized for the fourth time the metabolic rate was $+35$ per cent and the thyroid gland was distinctly smaller than it had been previously. Treatment with 0.6 Gm of thiouracil daily was begun. The metabolic rate fell to $+13$ per cent in twelve days when the dosage was reduced to 0.4 Gm daily. On the thirty-second day the dosage was further reduced to 0.2 Gm daily and on the thirty-ninth day the basal metabolic rate had fallen to -8 per cent. This dosage was continued and the patient returned to work. During this time the thyroid gland slowly increased in size to approximately that noted at the beginning of treatment. The patient has continued to take

Chart 1—Changes in the basal metabolic rate, serum cholesterol level, body weight and degree of glycosuria in case 1 during four periods of treatment with thiourea and thiouracil. Insulin was discontinued on July 21. The broken lines represent periods when the patient was not under observation in the hospital.

0.2 Gm of thiouracil daily and has remained in good health for a period of two months.

CASE 2—A man aged 37, a truck driver, first noted symptoms of nervousness, anxiety and tremor following an automobile accident five years before entering the hospital. After three years of moderate symptoms he began to lose weight and to tire easily. Toxic diffuse goiter was diagnosed on his examination for entry into the army and he was referred to the hospital for treatment. At this time he had lost a total of 35 pounds (16 Kg) but was not acutely ill. There was moderate exophthalmos and a pronounced stare but minimal lid lag. The skin was warm and moist, the thyroid gland was diffusely enlarged, soft and not nodular. The basal metabolic rate was $+45$ per cent on the first day and $+26$ per cent after three days of rest in bed. The serum cholesterol was 84 mg per hundred cubic centimeters. All other findings were essentially normal. Thiouracil was given in a dose of 0.2 Gm five times daily for twenty-seven days and then 0.4 Gm five times daily for six days. Symptomatic improvement became apparent during the second week of treatment; the serum cholesterol increased to 206 mg per hundred cubic centimeters and although the metabolic rate steadily decreased it did not reach normal levels. The body weight increased 20 pounds (9 Kg) during four weeks (chart 2). When the dosage of thiouracil was increased to 2 Gm daily the patient began to suffer vague malaise which he did not admit until subsequently. He was discharged from the hospital on the thirty-fifth day of treatment and was to continue to take 1.0 Gm of thiouracil daily. Within thirty-six hours of leaving the hospital he returned with a severe pharyngitis and a temperature of 105 F.

There proved to be no demonstrable granulocytes in the blood smear and the total white cell count was 1,100. The drug was discontinued and he was treated with sulfathiazole, liver extracts and pentnucleotide. After a severe illness he recovered, granulocytes returned in normal numbers after being absent from the blood smear for seven days. The patient was given 1 cc of compound solution of iodine daily following

Chart 2—Effect of a large dose of thiouracil on the basal metabolic rate, serum cholesterol level and body weight in case 2. During the first seven days of treatment symptoms of toxicity developed.

this episode but the metabolic rate returned to levels of +30 to +40 per cent three weeks after the thiouracil was discontinued.

CASE 3—A woman aged 43, a housewife, had been treated for hyperthyroidism for five years. Three years prior to the current episode subtotal thyroidectomy was performed with subsequent complete relief of symptoms for a period of nine months. Nervousness, irritability and general malaise then returned and continued to be of major concern; treatment with iodine, phenobarbital and estrogens brought no relief. The basal metabolic rate during this period was +20 per cent and the patient was 15 pounds (6.8 kg) under her normal weight. The thyroid gland was not palpable, and there was a moderate degree of stare but no exophthalmos. The skin was warm and the face flushed. Thiouracil was given in a dose of 0.2 Gm three times daily while the patient continued to work at home. After one week of treatment there was a noticeable improvement in the nervous irritability and the patient noted a general sense of well being. The basal metabolic rate fell in fourteen days to +7 per cent and in thirty-five days to -6 per cent. One week after the drug was discontinued the basal metabolic rate was -4 per cent and in five

Chart 3—Decrease in the basal metabolic rate and increase in body weight following the administration of thiouracil in case 3. Five weeks after the drug was discontinued symptoms returned and the metabolic rate became elevated. A second course of treatment with 0.2 Gm of thiouracil daily during March resulted in a decrease in the basal metabolic rate to +3 per cent and a further increase in the body weight to 152 pounds (69 kg).

weeks +17 per cent (fig 3). Symptoms returned during the fourth week but there was no loss of weight. Thiouracil was resumed in a dose of 0.2 Gm daily; symptoms were again controlled after one week of treatment, the metabolic rate returned to normal and the patient has remained well on this treatment for two months.

COMMENT

These preliminary studies indicate that thiourea and thiouracil may be useful in the control of hyperthyroidism. However, a true evaluation of the merits and dangers of such therapy will require the observation of a large number of cases over a prolonged period of time.

Compounds of the type used in this investigation have never before been administered to human beings except in isolated instances when small single doses were given for studies on intermediary metabolism. Possible toxic reactions of an acute or chronic nature may occur and in the few cases thus far studied one severe and several mild episodes were observed. The occurrence of agranulocytosis (case 2) is a most serious contraindication to any form of drug therapy, and it will be of importance to determine whether this type of reaction to thiouracil represents an idiosyncrasy or whether it is the result of too large a dose. Thiourea is apparently the least toxic substance of the entire series but for clinical purposes it has the disadvantage of imparting a characteristic odor to the breath, and with some persons it is disagreeable to the taste. The only evidence of toxicity thus far encountered with thiourea was a skin rash in case 1. Thiouracil is apparently free of these disadvantages, and although it is more active it may prove to be more toxic.

There appears to be a variable latent period following the initiation of treatment before the metabolic rate begins to fall, and a similar although somewhat shorter period before clinical improvement is subjectively and objectively apparent. This delay in the effect accords well with the experiments in animals that have been referred to in which it was noted that the lowering of metabolism coincided in time with a complete or nearly complete loss of detectable colloid from the thyroid gland. If the concept that these drugs prevent the synthesis of thyroid hormone is correct, one might expect that the rate of metabolism would remain nearly constant as long as the store of thyroid hormone in the gland was adequate to supply the organism. When this store nears exhaustion, the decreased rate of thyroid hormone synthesis becomes apparent in the fall of the basal metabolic rate. Support for this explanation is given by the failure of 4 persons with normal thyroid glands to show a decrease in metabolism when the drugs were administered for periods of two to four weeks, while the cases of hyperthyroidism responded within ten to fourteen days. It is known that the store of thyroid hormone in hyperplastic glands is greatly decreased, while that of the normal thyroid is sufficient, if steadily released, to maintain the metabolism of a normal person unchanged for a period of one to three months. As the hyperplastic gland is presumably secreting at an increased rate, one might reasonably expect that its small store of preformed hormone would become exhausted much more rapidly than would that of a normal gland.

Further studies will be necessary in order to determine the optimal therapeutic regimen for long term treatment. Certain cases of hyperthyroidism will probably require treatment over many months or even years, while in other cases the state of hyperthyroidism is apparently temporary and self limited. It may be possible by the use of drugs of this type to maintain such patients in normal health during this period of temporary disturbance.

A rough estimate of the required dosages of thiourea and thiouracil may be formed from the data given. A daily dosage of 0.4 to 0.6 Gm of thiouracil would appear to have been adequate for the initial treatment of the elevated rate of metabolism in cases 1 and 3, and 0.2 Gm daily appeared to be an adequate maintenance dose in case 1. Possibly as much as 1.0 Gm daily is excessive and from case 2 it is apparent that 2.0 Gm daily was not more effective than 1 Gm. It may be that this large dose contributed to the severe toxic episode which followed.

Thiourea is about one third as active as thiouracil when tested in rats and therefore 1 to 2 Gm daily of the former might be considered an adequate dose for initial therapy with about 0.5 Gm daily for maintenance. In case 1 a maintenance dose of 1.5 Gm daily of thiourea was too large as symptoms and signs of early myxedema resulted after a period of five weeks and there was evidence of chronic toxicity in the form of a skin rash. A simple chemical method for the determination of the concentration of these substances in the blood might prove to be of value in estimating the proper dose by offering a means of comparison with the more exact determination of dosage requirements that can be made on experimental animals.

In the few cases treated thus far thyroid enlargement has not been observed with the possible exception of case 1. In this instance there was a distinct decrease in thyroid size when treatment was discontinued and a return of a slight enlargement when treatment was reinstituted. The human thyroid gland usually responds slowly with change in size and perhaps it was to be expected that little detectable enlargement would occur during a period of only a few months of drug therapy.

These results are considered to be further evidence that thioureylene derivatives inhibit the formation of thyroid hormone and that they may be employed in the treatment of hyperthyroidism.

SUMMARY

The daily administration of 1 to 2 Gm of thiourea or of 0.2 to 1 Gm of thiouracil to hyperthyroid persons resulted in the relief of symptoms and the return to normal of the serum cholesterol and the basal metabolic rate. There were observed a latent period of one to two weeks before these effects occurred, a sustained remission during treatment and a return of hyperthyroidism when therapy was discontinued.

25 Shattuck Street

Tons of Saltpetre—Man needs 8 Gm of nitrogen daily since protein is a nitrogen compound and the body uses up 50 Gm of protein daily which must be replaced. Since protein is essential for the building of protoplasm no creature can live without nitrogen. An animal can be overtaken with foods lacking in nitrogen such as fat, sugar and starch yet it will die because it cannot build up its necessary proteins. On the other hand however a dog can be kept alive on a diet consisting exclusively of amino acids, the nitrogenous compounds from which proteins are constructed because fats and carbohydrates, the two other chief constituents of the body, can be formed from protein. The quantity of nitrogen contained in the atmosphere surrounding the earth is immense. It has been estimated that 12 billion tons of saltpetre could be obtained from the air over the city of London. With this quantity the nitrogen needs of the world could be satisfied for several thousand years.—Kahn Fritz, *Man in Structure and Function* volume 1 translated from the German and edited by George Koehn M.D. New York: Alfred A. Knopf 1943.

A COMBINED METHOD FOR THE TREATMENT OF DELAYED MENSTRUATION

AND A TEST FOR EARLY PREGNANCY
A PRELIMINARY REPORT

HAIG CARAPETYAN, M.D.
NEW YORK

Many drugs and endocrine products which have been used for the purpose of inducing menstrual flow may be considered harmful when administered to a woman in whom amenorrhea is due to early pregnancy. At one time or another probably every obstetrician and gynecologist has experienced difficulty in distinguishing between delayed menstruation and early pregnancy by physical examination especially when facilities for laboratory diagnostic procedures have not been available. After treating 57 cases of menstrual delay with prostigmine methylsulfate I have gained the impression that this drug offers a possible solution to both aforementioned problems in selected cases.

The rationale for prostigmine therapy in menstrual delay is found in the premise that in the physiology of normal menstruation the events which lead to the ultimate appearance of menstrual bleeding are initiated or at least preceded by a state of hyperemia of the uterine tissues. This hyperemia is always present in the cyclic menstrual flow and is produced by estrogenic substances which acting on the uterus release acetylcholine in this organ. The acetylcholine thus produced in turn causes vasodilatation. It has been demonstrated that this hyperemia is under the control of the parasympathetic nervous system and that nonspecific chemical agents can produce hyperemia in the uterine tissues similar in all respects to that resulting from the action of estrogenic substances.¹

Since uterine hyperemia seems to be an important as well as a constant feature of normal cyclic menstrual bleeding in women it may be that a temporary absence of adequate hyperemia, due to lack of vascular responsiveness may well be a factor in the delay of menstruation in some cases endocrine function per se being perfectly adequate. In addition if the fact is considered that the parasympathetic division of the autonomic system controls uterine hyperemia then such important conditions as physical, mental and emotional strain may exert a decided influence on the menstrual cycle in women in whom there is no evidence of endocrine deficiency and in whom the organic disease is not a contributing factor.

At any rate assuming that diminished acetylcholine in the uterine endometrium and consequent lack of adequate vascularity of this organ is the causative factor in a given instance of menstrual delay it would seem logical either to increase the acetylcholine content by administering this drug or to potentiate the action

of that amount of the drug which is already present in the tissues. Prostigmine accomplishes the latter, theoretically if not actually, through inhibition of cholinesterase the tissue enzyme which destroys acetylcholine. Needless to say any drug which would exert a damaging effect on pregnancy would be highly objectionable. Preliminary experiments on impregnated rats had

* Subsequent clinical observation confirmed the presence of pregnancy

established the safety of this drug when it was administered in excessively large doses. These animals continued to full term pregnancy, producing normal and healthy litters. The same results were obtained when prostigmine was given to women in various stages of pregnancy. In no case was there an abortion or premature labor, and no other untoward side effects were noted.² With this assurance the present study was begun.

PROCEDURE

Each patient who presented herself for the treatment of delayed menstruation was subjected to a careful history taking and physical examination. After endocrine disorders and organic diseases were ruled out, as many of these women as could arrange it, about 70 per cent of the total, were given a Friedman modification of the Aschheim-Zondek pregnancy test in order that early pregnancy might be either ruled out or established. All of the Aschheim-Zondek tests were performed before the administration of the treatment.

Each patient received an injection of 1 mg. of prostigmine methylsulfate on three consecutive days. If the menstrual flow was established after the first or second injections, further treatments were deemed unnecessary. If no menstrual flow occurred within seventy-two hours after the last injection, a tentative diagnosis of pregnancy was made until this state was confirmed by an Aschheim-Zondek test or subsequent clinical observation. The ages of the patients ranged from 19 to 49. Women who, regardless of their age, had long standing records of irregular menstruation, and those in whom the amenorrhea was definitely due to an endocrine dysfunction or organic disturbance, were considered unsuitable for treatment. Nevertheless, for the sake of completeness of the study, a number of such cases were included.

RESULTS AND COMMENT

In this study of 57 cases prostigmine methylsulfate was used as a therapeutic agent in delayed menstruation and was found to be successful in inducing a normal menstrual flow in all women who were not pregnant.

2 Soskin, Samuel, Wachtel, Hirs, and Hechter, Oscar. The Treatment of Delayed Menstruation with Prostigmine. A Therapeutic Test for Early Pregnancy, J. A. M. A. 114: 2090 (May 25) 1940.
3 Robins, Spotswood. Prostigmin in the Induction of Labor, Virginia M. Monthly 67: 374 (June) 1940.

The results were uniform and no ill effects were noted. While I was utilizing this drug as a therapeutic measure for delayed menstruation, its value as a diagnostic procedure in early pregnancy was observed, and its accuracy as a diagnostic test for early pregnancy was compared favorably to the Friedman modification of the Aschheim-Zondek test. All women who were not pregnant, and whose Aschheim-Zondek test was negative before, menstruated normally following prostigmine administration. No ill effects were observed in early or late pregnancies. All Aschheim-Zondek positive women and all others not subjected to the Aschheim-Zondek test, but in whom the state of pregnancy was confirmed by subsequent clinical observation, successfully continued their pregnancies. In fact, at the time this report was compiled, some of these women had already delivered normal healthy babies. Of 18 patients who did not have the Aschheim-Zondek test, 5 in whom the amenorrhea had existed from five to sixty days gave clinical manifestations of early pregnancy. These patients did not menstruate after the administration of prostigmine. Subsequent clinical observations confirmed the presence of pregnancy in these women. All the patients who had amenorrhea, and whose previous menstrual history had been relatively normal, but who failed to menstruate after treatment with prostigmine, were tentatively diagnosed as pregnant and subsequent clinical events substantiated this diagnosis. No errors were noted.

The menstrual flow induced by the treatment did not differ in any manner from the normal as to the amount, quality and character. An occasional woman reported a slightly increased flow during the first and second days of the period.

The number of injections required to induce menstruation varied somewhat. The majority of the women required three injections, some menstruated after two injections, and in others the flow followed after the first injection. An occasional woman required four injections.

The time of the onset of menstruation following the treatment ranged from a quarter of an hour to seventy-two hours, the average time for the entire group being seventeen hours and thirty-two minutes after the last injection.

Prostigmine as a therapeutic measure for amenorrhea had no effect on those women whose past menstrual

TABLE 2—Patients Who in Addition to Their Previous Records of Menstrual Irregularities Also Manifested Endocrine Deficiencies and Other Organic Diseases

Age	Delay in Days	Aschheim-Zondek Test	Menstruation	Pregnancy
20-30	21-140	Negative	None	None

history was marked by extreme irregularities and who manifested evidences of endocrine deficiencies with obesity, male distribution of pubic hair or concomitant organic disease. Three such cases were treated. In each the Aschheim-Zondek test was negative, yet none responded to treatment. Later a large number of such cases were treated with similar results. This would seem to indicate that prostigmine is effective in only those women whose previous menstrual histories have been more or less regular and who have had no severe endocrine disturbances or organic diseases. Its use as a therapeutic agent in delayed menstruation should be confined to this type.

Some of the cases are briefly presented because of their interesting features

CASE 34—A married woman aged 29 nullipara nulligravida, with negative Aschheim-Zondek test gave a history of regular periods of twenty-eight to thirty days and five day duration until March 1, 1941. In the course of the following six months she had only slight spotting for two or three days, occurring at the time of the expected period each month. When she presented herself for the treatment, even this spotting had been delayed for thirty days. She was given 1 mg of prostigmine methylsulfate daily for three consecutive days. Seven days after her last injection she began to menstruate normally for the first time in seven months. When last seen she reported that she had had two more normal periods of twenty-nine day interval and of five day duration.

CASE 60—A married woman aged 37, tertipara quadri-gravida, whose uterus appeared to be the size of at least a four month pregnancy but the fundus was firm and irregular in shape and the cervix was not soft, was diagnosed as having myomata uteri. Interestingly enough, the patient was scheduled for operation, and she was advised to be treated at the clinic in preparation for the operation. While she was receiving treatments, she reported that her menstruation was delayed ninety days. Even at that time the appearance of the uterus and the cervix was not indicative of pregnancy. Nevertheless, because of her amenorrhea she was given three injections of prostigmine methylsulfate. No menstruation followed. On the basis of previous experience, diagnosis was changed to myomata uteri and pregnancy. An Aschheim-Zondek test was performed. It was reported to be positive. Thus the hysterectomy was deferred and the patient was referred to the obstetric clinic for proper treatment. In this case the therapeutic test for delayed menstruation was of definite value in a situation in which the clinical manifestations of pregnancy were confused.

CASE 52—A single woman aged 26, nullipara, nulligravida, had a regular menstrual cycle of twenty-seven day interval and seven day duration. She suffered from severe dysmenorrhea, very profuse flow and a large number of clots. The clinical and physical examination did not reveal any pathologic condition in the pelvis. There was no history of delayed menstruation. However, her peculiar problem was that she expected to have her next regular menstruation in ten days, but her wedding day was also scheduled for the same day. Because of unusual circumstances over which she had no control, the wedding day could not be changed. She wished to receive treatments in order to advance the date of her menstruation by several days. She was given 1 mg of prostigmine methylsulfate daily for four consecutive days. Twelve hours after the last injection she started to menstruate. This menstrual flow was remarkable in that it was induced six days in advance of the expected date in a woman whose menstrual history had been extremely regular. Furthermore, she reported that for the first time in her life the flow lasted only five days instead of the usual seven was free of all discomfort and there was a complete absence of clots. Of further interest was the fact that the two subsequent periods occurred at exactly twenty-eight day intervals and each lasted only five days, with normal flow, no clots and no discomfort. This patient is under observation.

CASE 17—A woman aged 18, nullipara nulligravida had severe dysmenorrhea since the onset of catamenia. At the time she applied for medical treatment her menstruation was delayed by fifteen days. She was given 1 mg of prostigmine methylsulfate. Normal menstrual flow followed four hours after the administration of the drug. This period and the following one were free of discomfort.

Granted that some patients might have menstruated even if they had not received prostigmine, nevertheless such consistently uniform results can hardly be disregarded. This combined method for the treatment of delayed menstruation and a test for early pregnancy seems of practical value and a perfectly safe procedure to use, no ill effects on the pregnant or the nonpregnant woman having been observed.

SUMMARY

A nonspecific chemical agent, prostigmine, which is pharmacologically and physiologically related to physostigmine has been used for the treatment of delayed menstruation, and its diagnostic value as a test in early pregnancy observed.

1 Hyperemia of the uterine tissues is essential in the cyclic menstrual bleeding.

2 Estrogenic substances release acetylcholine in the uterus, and the latter drug produces hyperemia in this organ.

3 Certain nonspecific agents have the property of potentiating the action of acetylcholine which is already in the tissues, thus causing hyperemia of the uterus and inducing menstrual flow.

4 This property of prostigmine was utilized in the successful treatment of delayed menstruation, and the method was found to be safe.

5 Absence of menstruation following treatment of suitable cases with prostigmine is considered indicative of the presence of pregnancy. The procedure may be used as a diagnostic test for pregnancy.

6 Prostigmine has no value in delayed menstruation when amenorrhea is due to organic diseases and endocrine deficiencies.

FAMILIAL ERYTHROBLASTIC ANEMIA
THALASSEMIA—COOLEY'S
ANEMIA

NOTES ON ITS PRIMITIVE TREATMENT

CAPTAIN ARIE C VAN RAVENSWAAY
MEDICAL CORPS, ARMY OF THE UNITED STATES

CAPTAIN KENNETH H SCHNEPP
MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

CARL MOORE, MD

Associate Professor of Medicine Washington University Medical School
ST. LOUIS

Since Cooley's¹ definite crystallization of a group of clinical findings as a disease entity, familial erythroblastic anemia has received worldwide recognition and confirmation. Cooley stressed a congenital cause, evidence of bone marrow stimulation leukocytosis, absence of increased fragility of the red blood cells, splenomegaly, osteoporosis and a peculiar mongoloid facial appearance.

As reports of cases appeared, the scope of investigation widened until it became clear that familial erythroblastic anemia was in reality a severe and usually fatal form in childhood, of what is essentially a hereditary, chronic disease of Mediterranean races, characterized by splenomegaly and certain characteristic changes in the blood. In fact, this greatly widened concept of the disorder led Whipple and Bradford² to suggest the name "thalassemia" or "Mediterranean disease" rather than the term 'erythroblastic anemia'. Indeed

Prepared under the direction of Col. James R. McDowell, Commanding Officer, Station Hospital and Post Surgeon, Jefferson Barracks, Missouri.

in our opinion the latter term cannot help but become confused with fetal erythroblastosis. The use of the word anemia is also misleading, since many of these patients may never exhibit a significant degree of anemia.

Fig 1—Appearance of some of the hundreds of tiny scars on the torso the result of seven years of primitive "cupping"

As now interpreted,³ this is a familial hemopoietic disorder occurring among the Mediterranean races. The cases reported have been found in persons of Greek, Armenian, Italian or Sicilian parentage. It is seen in its most severe form in childhood, in which it is characterized clinically by fever, continuous or intermittent, and is frequently associated with chills. There is severe splenomegaly and often severe hepatomegaly. The skin is icteric without bilirubin. This appearance is probably due to the deposition of an iron-containing pigment in the skin as well as in all internal structures and is comparable to that found in hemochromatosis.⁴ A typical mongoloid facies has been described. The blood picture is characterized by severe anemia which is hypochromic, microcytic and erythroblastic in type. Polychromatophilic, stippled and "target" cells⁵ and occasionally normoblasts are found in the circulating blood. The red cells possess an abnormally increased resistance to hemolysis by hypotonic solutions of sodium chloride. Osteoporosis can frequently be demonstrated in the long bones and skull by x-ray examination, and as the condition progresses it is gradually altered by the appearance of a compensatory lamellar striation which tends to replace the marrow.

⁵ Barrett, A. M. Special Form of Erythrocyte Possessing Increased Resistance to Hypotonic Saline. *J. Path. & Bact.* 46: 603-618 (May) 1938.

This form of the disease appears in infancy as early as the second month and usually terminates in death within a few years. There are all gradations from this to a type found in which the inherent defect is not so pronounced. There may be little or no anemia, fever or positive physical manifestations. In many instances the only stigma of the disease is an increased number of target cells in the circulating blood and an abnormal resistance of these cells to hemolysis. This phase of the disease is not incompatible with life, but the patients frequently complain of malaise and lack of strength. It is, however, often interspersed with episodes of anemia, increased weakness, chills and fever and susceptibility to intercurrent infection.

An effective treatment has not been found. Iron and liver therapy are of no benefit. Splenectomy tends to increase the anemia and is thus contraindicated.²

Death generally results from cardiac decompensation, secondary infection or the development of a hemorrhagic type of thrombopenic purpura.

Campanopetros⁶ has studied the familial transmission of this disease in a focal area in Sicily. His observations indicate that it is transmitted as a mendelian recessive characteristic.

REPORT OF CASE

G. P. P., born Jan. 12, 1908 in Vroulia, Sparta, Greece, was admitted to the hospital on Sept. 17, 1942 with the statement that he was suffering from familial erythroblastic anemia. His chief complaints were shortness of breath on exertion, weakness and periods of rapid pounding of the heart. Before his induc-

Fig 2—Smear of patient's blood. Several typical target cells are present.

tion into the Army on Aug. 22, 1942 he operated a candy store and restaurant. His story was interesting.

Vroulia is a small town in Greece within a half hour's walk of the Mediterranean. When the patient immigrated to the

⁶ Campanopetros, J. Recherches sur l'anémie érythroblastique infantile des peuples de la Méditerranée orientale, étude nosologique. *Ann. de med.* 43: 27-61 (Jan.) 1938. Recherches sur l'anémie érythroblastique infantile des peuples de la Méditerranée orientale, étude anthropologique, étiologique et pathogénique, la transmission héréditaire de la maladie, *ibid.* 43: 104-125 (Feb.) 1938.

United States about 1922 his home town had a population of about 700 people. In his grandfather's time the town boasted 1,200. Despite natural increases, the graveyard had been filled by the ravages of this disease, which the patient had learned to accept with a fatalistic sort of philosophy. In his part of Greece it is called *ellodous peretous* (ellodous peretous), literally chills-fever-blood disturbance. (The spelling and translation are the patient's.) It was a chronic wasting disease marked by bouts of chills, fever, sweating and "big stomach." Most of the newborn died within a year or two and many who lived were sickly specimens. The differentiation from malaria was simple: one took quinine if the chills and fever stopped, it was malaria.

The patient's paternal grandfather had been very thin and had had a "big stomach." Also occasionally he had coughed up blood. He died at about 45 years of age during the last five years of his life he had been out of his mind. His wife had left as her legacy the reputation of having the "big stomach" bigger than any one else's. She had six children, four of whom apparently died of "ellodous peretous," three of these during early childhood and one a son shortly after his marriage. There remained then the patient's father and uncle. The uncle died in 1936 approximately at the age of 50. The remains had been sent to the University at Athens for an autopsy, the result being understood by the family to have revealed a "cancer in the spleen." The uncle's wife died at the age of 28 of unknown causes, but she left an only male child who had been born paralyzed and, by diligent hand feeding, had reached the age of 15 without walking or talking. The patient's father is still living at the age of 67. He has leakage of the heart and rheumatism. During childhood he was bothered by a large spleen but recovered. This condition recurred at 21 years of age, and he was bedfast until he was 29, when he practically recovered. Even yet he has occasional chills.

The patient's mother was said to have had a relatively severe form of the disease and she died at the age of 47 with a greatly swollen abdomen. Most of her life her weight did not exceed 80 pounds (36 Kg). She bore three sons and three daughters and in many respects must have been an unusual woman. She served as the midwife of Vroulia, and since there was no physician within many miles, she was called on to treat everything and anything that presented, in addition to delivering a multitude of ill-fated babies. She had her own ideas concerning "ellodous peretous" and believed it to come from bad air. She originated her own methods of treatment, believed in them and assiduously applied them to her children.

One of the patient's brothers died in Chicago of meningitis at the age of 15. Although born in Greece he did not appear ever to have had an enlarged spleen. Another brother is 17 and almost blind of unknown cause. He has severe anemia and his spleen is said to have been palpated on different occasions. One sister is living and well at 36 with no evidence of an enlarged spleen, although she was born in Greece. Another sister born in Greece, died in Chicago at the age of 22 of anemia with an enlarged spleen. The sister who died at the age of 23 presented an almost identical condition.

The patient is mildly surprised that he is alive. He was a sickly infant who could retain little food and hence was breast fed by his mother to the age of 4, when he stood alone for the first time. The first tooth appeared at 4½ years of age. For some time after this he was fed on diluted goat's milk. During his early childhood bouts of chills and fever were frequent for which his mother had adopted the unique but time honored treatment of bleeding. Her method involved the lifting of five or six folds of skin in close proximity over the liver or spleen and making each with a knife. Then a tumbler was pressed over this area with a lighted piece of cotton inside. This consumed the oxygen and created a suction. These tumblers were left in place until they loosened of themselves, which was usually when about a third full of blood. As many as four or five tumblers would be used at one time. This procedure would be repeated at intervals during episodes of chills and fever and went on in the patient's case, for seven or eight years. His torso is covered with literally hundreds of tiny scars (fig 1). One sister endured this treatment for sixteen years.

Another striking form of treatment was that applied to the spleen. The children were taught to lean over any sharp edged piece of furniture, such as a table, and compress the spleen for as long as they could endure the resulting pain. The patient stated that a favorite method of his was to hook the edge of the spleen over the top edge of a fence and literally hang by the spleen both feet off the ground. Spartan treatment, but the resulting improvement in his breathing would cause him to repeat this six or eight times a day.

At the age of 14 the patient and his father came to America on a freighter. He was so pallid that he spent hours on the boat pinching his cheeks to bring out some color. He was allowed admittance to Ellis Island only because he convinced the physician that he had been the victim of severe seasickness throughout the entire twenty-eight days of the voyage.

The patient does not specifically recall any childhood diseases. He had a tonsillectomy in 1923. Except for bouts of chills, fever and weakness he had no serious illness until 1939. At this time he had a "weak" period of typical chills, fever, enlarged spleen and anemia. An infection of the upper respiratory tract followed and was complicated by pleurisy with effusion on the right side. Spontaneous resolution occurred during a nine week stay in bed. However dyspnea was severe because of the effusion and enlarged spleen. Mindful of his mother's teaching he would spend hours leaning forward and partially hunched over a large shoe pressed against his spleen.

On physical examination most of the findings were not remarkable. The skin was a peculiar yellowish tinged muddy color, and the spleen was palpated 2 cm below the costal margin. The skin of the torso was covered with hundreds of tiny scars. X-ray examination of the skull, humerus, femur and hands revealed no abnormality. Gastric analysis revealed a free acidity of 15 and a total acidity of 25.

One of us (C M) made detailed studies on blood and bone marrow (obtained by sternal puncture) with the following results:

red blood cells 4,970,000 hemoglobin 14.2 Gm or 92 per cent, platelets 894,000, reticulocytes 1.0 per cent, white blood cells 16,550 with the following differential count: basophils 1 per cent, eosinophils 2 per cent, stab cells 1 per cent, segmented cells 67 per cent, lymphocytes 20 per cent and monocytes 9 per cent. The white cells all appeared qualitatively normal and the red cells showed no significant variation in size. A large number of the cells, however, were typically target red cells (fig 2). Venous blood showed a red cell count of 5,080,000, hemoglobin 13.8 Gm and an actual packed red cell volume of 45 per cent. The indexes calculated from these values gave a mean corpuscular volume of 89 cubic microns (normal range 80 to 94), mean corpuscular hemoglobin 27 micromicrograms (normal range 27 to 32) and a mean corpuscular hemoglobin concentration of 31 per cent (normal range 33 per cent to 38 per cent). The fragility test showed a range of 0.38 to 0.25 as compared with the normal value of 0.42 to 0.30. There was therefore evidence of increased resistance of the red cells to hypotonic saline solution. The sternal marrow removed by aspiration was very cellular and was characterized by normal distribution of qualitatively normal myeloid and erythroid elements. There were no truly abnormal characteristics of the marrow and it could easily be easily passed as being perfectly normal.

The patient's wife, aged 27, whom he married in 1933, was born in this country and has never had any evidence of

Fig 3.—Appearance of the daughter of the patient shortly before her death from familial erythroblastic anemia, showing the characteristic mongoloid facies.

CONCLUSIONS

The importance of an early diagnosis in cases of tick paralysis has been made clear in the preceding discussion.

The demonstration of the American dog tick as the etiologic agent in 4 cases of tick paralysis has made widespread knowledge and recognition of this syndrome most essential.

With the realization that *Dermacentor variabilis* Say is commonly found throughout the eastern part of the United States and that although usually found on the dog, there are numerous other known hosts,⁸ it is evident that especially in rural districts tick paralysis should always be considered among the diagnostic possibilities in the presence of an ataxia or of an ascending flaccid paralysis of sudden onset.

NEUROCIRCULATORY ASTHENIA

MAJOR IOLIS I. BISHOP, JR.
MEDICAL CORPS ARMY OF THE UNITED STATES AND
FIRST LIEUTENANT ROBERT W. KIMBRO
MEDICAL CORPS ARMY OF THE UNITED STATES

The diagnosis of neurocirculatory asthenia may often be difficult to detect in the routine examination of candidates for induction into the United States Army. It is not until the physical and emotional strain of war that an individual with neurocirculatory asthenia becomes incapacitated and finally through pensions and invalidism becomes a permanent financial burden to the Army.¹ These facts are illustrated by the following report:

REPORT OF CASE

History.—W. L., a private aged 45, was inducted into the Army in October 1942. Soon after this he reported on sick call and was admitted to the hospital with the following complaints: "pain in heart, shortness of breath, and heart skips beats." He stated that while at home he worked as a farmer, carrying out his usual duties without difficulty. At times he had some shortness of breath with exertion. It was discovered that he had been discharged from the Army at the time of the last war and had with him a Certificate of Disability for Discharge which he received Nov. 12, 1918 at Camp Travis, Texas, twenty-four years ago. This Certificate of Disability for Discharge stated: "W. L. is hereby discharged from military service of the United States by reason of Neurocirculatory Asthenia, pulse standing 144, lying 92, after exercise, 180 two minutes later, 120."

Physical Examination.—General physical examination in 1942 was negative. The blood pressure was 118 systolic, 80 diastolic. The pulse rate was 130 standing and 90 sitting, after exercise 156, and after two minutes rest following this exercise 120. The palms of the hands were moist and excessive axillary perspiration was noted. There was a coarse tremor of the fingers. The apex of the heart was diffuse at the fourth interspace in the midclavicular line. There were no murmurs.

The electrocardiogram was within normal limits. The heart was of normal size and shape. The aorta was moderately widened.

The diagnosis was neurocirculatory asthenia.

COMMENT

This case illustrates that there is no specific treatment for this clinical syndrome and that the return of this soldier to civil life after the last war did not in any way change his condition, his symptoms in this war paralleling exactly those he had in the last war. From his history it was ascertained that this man could make a fair adjustment to his life as a farmer but not as a soldier. As far as we know, this is the only example of a person with this condition who has been discharged from the same army in two wars.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

RUBBERLESS RESPIRATOR COLLAR
ACCEPTABLE

Manufacturer: R. L. Slater, 30 North La Salle, Street, Chicago

The Rubberless Respirator Collar is designed to fit all standard type respirators for use as the patient's neck seal to retain air pressures necessary for respirator operation. The development of the device is said to have come about as a result of research to discover a substitute for sponge rubber collars. Difficulty in obtaining sponge rubber collars is being encountered, and it is said that many respirators now in use are in need of collar replacement.

The device consists of a small wire coil spring (plated to prevent rusting) with ends soldered together to form a ring and covered by a soft closely woven fabric lined with an air tight plastic material. The lined fabric extends to the padded outer section of the collar, forming an air resisting surface with the spring action serving as a draw string around the neck. The padded section fits under the respirator metal collar clamp, permitting it to be firmly fastened to the respirator. As the result of the spring action the collar is less difficult to put on and take off than the sponge rubber collar.

The manufacturer asserts that the materials used in the construction of the collar are far more durable than sponge rubber. Air and sunlight have no apparent ill effects on the lasting qualities. The device can be easily washed and dried.

According to the manufacturer, the collars have been tested on respirators in use at several widely recognized institutions. Results of all these tests are said to be satisfactory.

In the Council's investigations the respirator collar was found to be installed on the respirator with even greater ease than the sponge rubber collar for which it is a substitute. The hole is readily made large enough to admit the head of an adult or a small child with less difficulty than is true of the rubber collar. Some little difficulty was encountered in getting a close enough fit in the case of a very small child. But by some manipulation this difficulty was overcome. On the whole, it was found that these collars are not only a satisfactory substitute for the rubber ones but may be superior.

The Council voted to accept the Rubberless Respirator Collars for inclusion in its list of accepted devices.

Rubberless Respirator Collar

AN APPRECIATION

The Council on Physical Therapy desires to take this opportunity to express its feelings of gratitude and appreciation of the services of the following consultants, whose assistance in carrying out the work of the Council has been given so freely during the past year:

Drs. Charles Bahn, Walter M. Boothby, Milton B. Cohen, Hart Fisher, John S. Hibben, K. K. Jones, S. L. Osborn, Lauriston Taylor, Ralph Waters and W. F. Wells.

Audiometers and Hearing Aids: Drs. C. C. Bunch (deceased), George M. Coates, E. P. Fowler, W. E. Grove, Dean Lierle, Isaac Jones, Walter Hughson, Douglas Macfarlan, C. Stewart Nash, Horace Newhart, Paul Sabine, B. R. Shurly and W. P. Wherry (deceased).

Educational Work: Drs. Frances Baker, Benjamin Boynton, Muriel Case Downer, Earl C. Elkins, F. H. Ewerhardt, Richard Kovacs, Fred B. Moor, W. H. Northway, William Schmidt, Walter M. Solomon, Arthur L. Watkins and Walter J. Zetter.

Artificial Limbs: Drs. S. Perry Rogers, Paul Steele and Philip Wilson and Messrs. McCarthy Hanger Sr., W. E. Isle, J. B. Koriady, Joseph Spievak and David E. Stolpe.

STATE BOARDS OF MEDICAL EXAMINERS

Statistical compilations regarding medical licensure are presented annually in the State Board Number of THE JOURNAL. In the following pages will be found the report for the year 1942, which constitutes the forty-first annual presentation. Data are included regarding (a) medical examining and licensing boards of the several states, the District of Columbia, the territories and possessions of the United States, (b) examining boards in the medical specialties, (c) boards of examiners in the basic sciences and (d) the National Board of Medical Examiners.

These computations are based on official records received throughout the year from the medical licensing boards of all the states, Alaska, Hawaii and the Virgin Islands, the homeopathic licensing boards of Connecticut, Delaware and Maryland, the seventeen boards of examiners in the basic sciences in operation last year, the fifteen approved examining boards in the medical specialties and the National Board of Medical Examiners. The homeopathic and eclectic examining boards in Arkansas and the homeopathic board in Louisiana did not license any one during the year.

The cooperation of the officers of the foregoing boards in making possible the vast amount of reliable information presented in the following pages is gratefully acknowledged. The Council and THE JOURNAL express their appreciation to those who have supplied these data.

From 1926 to 1938 the credentials presented by physicians from countries other than the United States and Canada were verified by official correspondence with the medical school directly or through the diplomatic service. For several years the Council has been unable to render this service, and on the licensing boards of the various states now rests the responsibility of evaluating the credentials presented by applicants claiming graduation from schools outside the United States. Later in this presentation statistics have been computed separately, recording physicians examined on the basis of certificates obtained in countries other than the United States and Canada.

The tables referring to medical licensing boards include figures regarding the number of candidates examined for medical licensure in 1942, the number licensed and the number added to the profession. The

state boards are discussed first, followed by the special examining boards, the basic science boards and the National Board of Medical Examiners.

LICENSES ISSUED

During the year 1942 8 457 licenses to practice medicine and surgery were issued by the medical examining boards of the forty-eight states, the District of

(Continued on page 92)

Because of the restrictions on paper it has been necessary to restrict publication of this material in THE JOURNAL. The complete report with omitted tables will appear in the reprint.

(Continued from page 89)

Columbia Alaska, Hawaii and the Virgin Islands Of the 8 557 licenses issued, 6,099 were issued after examination and 2 458 by reciprocity and endorsement of other state licenses or the certificate of the National Board of Medical Examiners

In twenty-two states, the District of Columbia, Alaska, Hawaii and Puerto Rico the internship is a requisite for practice, but a physician is permitted to take the examination on completing the medical course in most of these states, and, if successful, his license is withheld until the completion of the internship This practice is followed by recent graduates Licenses are also withheld for proof of citizenship and minor technicalities In some states also the licenses of physicians taking examinations scheduled in December are dated and issued early in the following year Tabulations in table 1, therefore, include many who were examined in 1941 and even a few in previous years Consequently, figures in this table will not correspond with those hereinafter given, which deal entirely with physicians examined for licensure within the year 1942

Four states issued licenses to more than 500 physicians, namely New York 1,330, California 740, Pennsylvania 516, Illinois 509 Twenty-five states, Alaska, Hawaii and the Virgin Islands licensed fewer than 100 physicians None were licensed by examination in New Mexico, Wyoming or the Virgin Islands The fewest number, 8, were licensed in New Mexico

An interesting point to observe is that in some states the number registered without examination far exceeded those required to write an examination On the other hand, in many states the reverse was the case The latter is particularly significant in New York, where 1,071 took examinations and 259 received licenses by endorsement of their credentials Louisiana issued only 26 of its 335 on the basis of credentials The state

of Florida grants licenses only on the basis of examinations Massachusetts, Rhode Island and Hawaii have no reciprocity agreements but endorse diplomates of the National Board of Medical Examiners

Totals for seven previous years and 1942 are shown for comparison in table 3 Since 1937, when the greatest number of licenses were issued, fewer have received licenses annually In 1942 the number registered decreased 255 This reduction can probably be charged in part to the fact that physicians have entered the armed forces immediately after graduation, although ten states granted more licenses than in previous years

TABLE 3—Licenses Issued, 1935-1942

	Examination	Reciprocity and Endorsement	Total
1935	5,725	2,194	7,919
1936	6,275	2,772	9,047
1937	6,629	3,204	9,833
1938	6,557	2,956	9,513
1939	6,400	2,872	9,272
1940	6,289	2,865	9,154
1941	6,053	2,759	8,812
1942	6,099	2,458	8,557
Totals	50,027	22,080	72,107

Notably, Louisiana registered 335 physicians in 1942 as compared with 157 in 1941 The intern year as a requirement for licensure was discontinued in Louisiana in 1942, and those who normally would have been licensed in 1943 obtained the certificate last year The University of Texas Medical Branch accelerated its senior year in 1942, this class receiving their degrees in December 1942 There was no notable change in the number of physicians licensed in Texas The University of Wisconsin Medical School dropped the requirement of a hospital internship for the duration of the war and awarded degrees in December 1942,

and surgery, those in the District of Columbia, Oregon and Wisconsin only in surgery. In Indiana the licenses issued to osteopaths authorized the holders to practice surgery and obstetrics. Connecticut examined 1 in medicine and 2 in surgery.

Of the graduates of unapproved schools, Massachusetts examined 272 and Illinois 54. One candidate was

TABLE 4—Source of Candidates Examined, 1942

Medical Schools	Number	Number Examined	Number Passed	Number Failed	Per centage Failed

Totals	200	7,180	6,076	1,104	15.4

also examined by the licensing boards in Mississippi and Hawaii. Mississippi also examined 2 undergraduates.

The total number (7,180) does not represent individuals, since a candidate might take the examination in more than one state and would be counted in each state. This applies to those who pass or fail or those who fail and later in the year pass in one or more states, or pass in one or more states and later in the same year fail elsewhere. A candidate failing more than once in a given state within the year is counted as one failure.

The greatest number of graduates of any one school examined was 163, representing Northwestern University Medical School, who were examined in twenty-six states. Of these, 161 were successful and 1.2 per cent failed. In another instance 153 graduates of Hahne-

mann Medical College and Hospital of Philadelphia were examined in sixteen states. Twenty-eight graduates failed to pass the licensing examination, representing 18.3 per cent of those examined.

Twenty-eight schools in the United States had no failures before medical licensing boards, twenty-four less than 5 per cent, eleven between 5 and 10 per cent, and three more than 10 per cent. The number examined from many of the schools having a high percentage of failures is small compared with the annual output of graduates of these schools. This is accounted for

by the fact that a good majority of their graduates take the examinations of the National Board of Medical Examiners. Table 10 includes figures and percentages of all examined during 1942, i. e. those who were examined by the National Board of Medical Examiners in their final examination as well as those passing state tests.

Graduates of Northwestern University Medical School and Harvard Medical School were examined in the greatest number of states—twenty-six. The University of Pennsylvania graduates were tested in twenty-four states, Jefferson Medical College in twenty-three states, Johns Hopkins and Temple University schools of medicine in twenty-two states respectively and the University of Chicago in twenty-one states. All other schools had their graduates examined in fewer than twenty states. The medical schools of the University of Georgia, New York Medical College, Buffalo, Baylor, Texas and Vermont had graduates examined in fewer than five states. No graduate of Albany Medical College took the state written examinations for medical licensure during the year.

Totals taken from this table are subdivided into five groups in table 4, namely approved medical schools in the United States and in Canada, schools no longer in existence, foreign faculties of medicine and unapproved institutions. Of the United States schools 2.4 per cent failed and of the extinct schools 5.4 per cent failed. Eighteen graduates of Canadian schools, or 19.4 per cent of the total examined, failed examinations in the United States. The greatest percentage of failures represented two groups—foreign faculties of medicine and unapproved schools. In these two groups 45.4 and 50.8 per cent, respectively, failed.

Three of the five homeopathic boards in existence, Connecticut, Delaware and Maryland, examined 11 candidates, all of whom passed. The homeopathic boards in Arkansas and Louisiana did not examine any one in 1942. The one eclectic board in existence, in Arkansas, did not examine a candidate.

Ninety-three graduates of nine approved medical schools in Canada were tested for medical licensure in the United States in 1942 in twenty-one states and the District of Columbia (table 5), of whom 75 passed and 18 failed. Twenty-five graduates of McGill University Faculty of Medicine and 22 of the University of Toronto Faculty of Medicine applied for licensure in eleven states, respectively, and in each instance 21 were successful. The highest percentage of failures (60) represented Laval University Faculty of Medicine, whose graduates were examined in three states, and the University of Montreal Faculty of Medicine in four states. Three Canadian schools had no failures before United States licensing boards. The state of New York examined 31 Canadian graduates. All other states testing graduates of the schools in Canada examined less than 10 and in the majority of states fewer than 5. Eleven were unsuccessful in the examination given by the New York board of medical examiners.

Graduates of medical schools of other countries were examined for licensure in twenty-four states and Hawaii. In 1942 also 440 graduates of unapproved schools were examined in eleven states and Hawaii.

Altogether in 1942 there were 7,180 candidates tested for medical licensure, of whom 6,076 passed and 1,104, or 15.4 per cent, failed.

Elsewhere are given figures referring to actual licentiates and additions to the medical profession.

GRADUATES OF 1940 1941 AND 1942 EXAMINED
FOR MEDICAL LICENSURE

In table 6 are presented figures recording graduates of 1940, 1941 and 1942 examined for medical licensure in 1942. Represented were 4,609 graduates of sixty-five approved medical schools in the United States, 48 graduates of nine approved medical schools in Canada, 191 recent graduates of medical schools outside the United States and Canada, and 320 graduates of unapproved schools. Altogether 5,168 graduates of the last three years were examined, of whom 4,876 passed and 292 or 5.7 per cent failed. The number who passed and failed in each of these four groups are given in table 7.

Of the medical schools of the United States 1.9 per cent failed, while among the graduates of the Canadian schools 18.7 per cent failed, those holding foreign degrees 30.9 per cent and unapproved schools 42.5 per cent.

Thirty-seven schools in the United States had no failures among recent graduates applying for licensure; twenty-one schools had less than 5 per cent and eight more than 5 per cent and ranging to 16.7 per cent.

The greatest number examined by any one state was New York 588, Pennsylvania examined 436, Cali-

TABLE 7—Source of Graduates of 1940, 1941 and 1942, Examined, 1942

Medical Schools	Examined	Passed	Failed	Percentage Failed
Approved in United States	4,609	4,321	288	1.9
Approved in Canada	48	39	9	18.7
Foreign	191	132	59	30.9
Unapproved	320	184	136	42.5
Totals	5,168	4,876	292	5.7

formia 402, Illinois 369, Texas 294, Ohio 266 and Massachusetts 245.

More than 100 from each of fourteen schools were examined, the highest being 182 graduates of the University of Texas Medical Branch, who appeared before licensing boards in two states, 181 in Texas and 1 in Arizona. The senior class of the University of Texas under the accelerated curriculum was matriculated in March 1942 and completed the course in December. While the latter graduates were examined late last year they did not receive their licenses until January 1943.

Only 12 of the recent graduates of the Yale University School of Medicine were examined last year, in seven states. Very few also of the recent graduates of the Boston University School of Medicine, Tufts College Medical School, the New York Medical College and Duke University School of Medicine applied for licensure by this method and none from Albany Medical College. The majority of the graduates of these schools with few examinees before state licensing boards obtained the certificate of the National Board of Medical Examiners and received state licenses to practice medicine by endorsement of this certificate.

The source of graduates of 1940, 1941 and 1942, respectively, examined for medical licensure last year are subdivided by years in table 8, giving totals passed and failed for (a) approved medical schools in the United States, (b) approved medical schools in Canada, (c) medical schools now extinct, (d) foreign faculties

of medicine and (e) unapproved schools. Of the graduates of 1940, 396 passed, while 1,350 graduates of 1941 and 3,130 who received their degrees in 1942 were successful. These totals together with percentages are again presented in table 9.

Of the total number of examinees for licensure in the United States in 1942 72 per cent were graduates

TABLE 8—Source of Graduates of 1940, 1941 and 1942 Respectively Examined for Medical Licensure, 1942

Medical Schools	1940		1941		1942	
	Passed	Failed	Passed	Failed	Passed	Failed
Approved in United States	2,500	16	1,160	44	2,000	26

of 1942, 1941 and 1940. Of those graduates prior to 1940, 40.4 per cent failed, whereas only 5.7 per cent of the recent graduates of all schools failed.

CONSOLIDATED EXAMINATIONS

In 1942, 4,905 graduates of approved medical schools in the United States were examined by medical licensing boards, of whom 2.4 per cent failed. In the same period 972 graduates of approved medical schools in the United States appeared for Part III of the examination of the National Board of Medical Examiners, of whom 1.2 per cent failed. A comparison of the failures in each group revealed that in some instances schools having a high percentage of failures before licensing boards had few, if any, failures before the National Board of Medical Examiners. Individual school results for these two groups are presented in table 10. In these consolidated figures the percentage of failures of approved medical schools in the United States was 2.2.

Of the Canadian schools, 19.4 per cent failed state board tests and 16.4 per cent the combined tests. Very little comparison is evident in this group, since only 17 graduates of two Canadian schools were examined by the National Board. Only 51 graduates of foreign faculties of medicine were tested by the National Board, while 1,630 were examined by state licensing boards. The National Board does not admit to its examinations graduates of other than approved schools.

TABLE 9—Graduates of 1940, 1941 and 1942 Respectively Examined, 1942

Graduates of	Examined	Passed	Failed	Percentage Failed
1940	476	396	80	16.8
1941	1,477	1,350	127	8.6
1942	3,210	3,130	80	2.6
Totals	5,163	4,876	287	5.7

The total of all examined before medical licensing boards was 7,180, of whom 6,076 passed and 1,104 (15.4 per cent) failed. For both groups 8,233 were examined, 7,116 passed and 1,117 (13.6 per cent) failed. The total percentage of failures has been slightly reduced by including figures for the National Board of Medical Examiners, but materially so for certain schools. Twenty-four schools had no failures in either group. The highest percentage of failures for one school was 18.1 per cent, the failures of the majority of schools averaging less than 3 per cent.

FAILURES BEFORE MEDICAL EXAMINING BOARDS

Data recorded in table 11 refer to the number who failed state board examinations and were graduates of a medical school located in the state in which they were examined, and, by comparison, the number of graduates licensed in the state who obtained their medical training in schools in other states. Most noteworthy is the fact that in New York state 39 per cent of those who studied medicine in eight schools in that state who appeared for licensure in 1942 failed, while

a much higher percentage 90 who obtained their medical training in forty-four schools located in other states failed. Yale University had no failures before the Connecticut medical examining board, while 12.2 per cent of the graduates of eighteen schools of other states failed in Connecticut. Only 41 physicians failed examinations in the state in which the medical school they attended was located, and twenty-two states had no failures from schools within their boundaries. There were 65 failures from schools located in other states. Thirty-three states reported no failures during the year. Six states (table 24) had no failures in five years. In some states an applicant must receive an

average of at least 75 per cent and not fall below 50 per cent in any one subject. In case of failure in not more than two subjects, the applicant is entitled to another examination in those subjects within twelve months. Those so failing are not reported to the office of the Council as failures. The highest percentage of failures was reported by North Dakota, 167. In this state 6 physicians representing four medical schools located in other states, were examined of whom 1 failed. Four states without medical schools reported eleven failures.

Of the 8,557 licentiates in 1942, 813 had previously been unsuccessful before a licensing board. Of the approved schools 100 graduates were licensed after one failure in the state of licensure and 53 after one failure elsewhere. Forty-two received licenses after more than one failure, 27 received licenses in the state of their previous failures, 11 succeeded in obtaining licenses after more than one failure elsewhere, while 4 licentiates had previously failed in the state where licensed and also in other states. Forty-two were licensed after more than one failure.

In another table presented in this group (table 12) is given the number licensed after failing a state board examination once and after two or more failures, these groups being classified by indication whether the failure or failures have been in the state in which they were receiving a license or elsewhere and also whether the failure has been in the state where licensed and elsewhere. These two divisions are given for three groups of candidates, namely graduates of approved medical schools, foreign faculties of medicine and unapproved institutions. The total number of candidates examined and licensed or granted licenses by endorsement or reciprocity in each state is also shown.

The graduates of foreign faculties of medicine who were registered after previous failures numbered 565 and those of unapproved schools 50.

In the computation of these statistics it was noted that 60 licentiates had failed five or more times. Of these 13 had five failures before obtaining a license, 19 had six, 10 failed seven examinations, 5 individuals failed eight tests, 1 failed 9, 2 failed ten, 3 failed eleven, 2 failed twelve and 2 failed thirteen examinations before being successful. Three graduates of European medical schools were licensed after eighteen, twenty and twenty-one failures respectively in Connecticut, New York and New Jersey. The majority of these physicians

with multiple failures were Massachusetts and New York examinees. Thirteen states licensed in 1942 only physicians who never failed a state board examination, while New York licensed 562 who had previously failed. With the exception of California, Illinois, Maine, Massachusetts, New Jersey, New York and Pennsylvania no state licensed more than 9 such candidates.

ments with any state. With the exception of Florida, however, these states and Hawaii will register diplomates of the National Board of Medical Examiners by endorsement. Those desiring licenses by reciprocity or endorsement in seventeen states are required to obtain a certificate from the state board of examiners in the basic sciences before being eligible for licensure.

Some states have additional requirements for graduates of schools outside the United States and Canada
+, indicates reciprocal or endorsement relationships have been established, - indicates no reciprocal or endorsement relationships have been established

- 1 1st P, first papers required ⊕, full citizenship required
- 2 In most cases there is a small additional recording or registration fee
- 3 If state of original license grants similar privileges
- 4 Internship accepted in lieu of one year's practice
- 5 Professional practice required
- 6 No professional practice required
- 7 Just preceding application
- 8 No basic science reciprocity—examination must be within the state
- 9 Basic science certificate required either by reciprocity or examination in addition to basic science subjects of National Board
- 10 Reserve officers not eligible
- 11 Leading medical schools of Great Britain recognized

- 12 Oral examination required when original license is ten or more years old
- 13 Applicant must have resided in the state used as basis of application for one year after date on said certificate
- 14 Oral examination required
- 15 Unless in practice in another state for five years
- 16 Actual practice for a period of three years immediately preceding date of application
- 17 Practical, clinical examination required
- 18 Foreign graduates only
- 19 Regular and Homeopathic boards
- 20 Graduates of foreign medical schools may be accepted if they present also a diploma from an approved medical school in the United States
- 21 Regular board
- 22 Fee same as applicant's state charges if more than \$50
- 23 Oral examination required if applicant's state requires it
- 24 If an applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

Charted in table 13 are the reciprocity and endorsement policies of the various states, the District of Columbia, Alaska, Hawaii and Puerto Rico. Four states—Florida, Idaho, Massachusetts and Rhode Island, as well as Hawaii, do not have reciprocal agree-

ments with any state. With the exception of Florida, however, these states and Hawaii will register diplomates of the National Board of Medical Examiners by endorsement. Those desiring licenses by reciprocity or endorsement in seventeen states are required to obtain a certificate from the state board of examiners in the basic sciences before being eligible for licensure.

cal practice acts give the examining boards the privilege of using their discretion in determining the acceptability of a candidate. The states in which diplomates of the National Board of Medical Examiners and retired officers of the government services are eligible for licensure on the basis of their credentials are also indicated. Specific requirements, such

are graduates of foreign medical schools accepted on a reciprocal basis. Other requisites or exemptions are mentioned in footnotes.

The credentials presented by physicians granted licenses in 1942 to practice medicine and surgery without written examination are given in table 14. There were 2,445 so registered on the basis of licenses issued

and Endorsement Policies

- 25 Internship accepted if served in this state
 26 Internship accepted—considered equivalent to two years' practice
 27 Five years' practice
 28 Conditionally
 29 A two year internship is accepted
 30 Diplomates of National Board not required to have been in practice for three years
 31 Graduates before 1907 required to take oral examination
 32 Clinical examination required
 33 Reciprocity applicants only
 34 Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established
 35 May be licensed after a special (written) supplemental examination
 36 Fee for license on basis of National Board certificate \$25
 37 For matriculants after Oct 15 1937
 38 Fee \$50
 39 While on active duty only

- 40 Permanent license withheld until completion of citizenship
 41 Graduates of foreign medical school effective Sept 15 1925
 42 Canadian schools exempted effective Sept 19 1929
 43 Graduates of foreign medical school are not accepted
 44 Graduates of foreign medical school must have fulfilled all requirements of California prior to admittance to examination for any certificate used as basis of application to California
 45 Graduates of approved schools of Canada eligible
 46 Not applicable to citizens of Canada
 47 Canadian citizens are required to file first papers
 48 Fee \$10
 49 Same as required of Utah candidate applying for licensure
 50 Diplomates are accepted on basis of reexamination. The questions and answer manuscripts from the National Board are submitted for regrading
 51 All applicants must be graduates of a medical school approved by the American Medical Association
 52 Reciprocity with all state if applicant is reputable graduate of an approved medical school

as professional practice, oral examination and internship, are recorded as is also the fee for a license without written examination. There is included a column outlining citizenship prerequisites. By footnote is indicated whether physicians of Canadian birth are exempt from the citizenship requirements. In very few states

by other states the District of Columbia, Canada and foreign countries.

The greatest number of licenses by this method was issued in California where 283 were registered. Five other states endorse more than 100 such candidates, namely, New York 259, New Jersey 128, Michigan 116.

TABLE 14—*Candidates Presented by Physicians for Licensing by Reciprocity and Endorsement 1912*

[illegible]

Massachusetts 111 and Texas 105. The largest group presenting the same type of credentials were the 702 diplomates of the National Board of Medical Examiners. 189 were registered on the basis of such credentials in New York and 111 in Massachusetts.

More than 100 physicians holding licenses from Illinois, Missouri, New York and Pennsylvania respectively were licensed in other states. No physician holding a Wyoming license applied for registration in another state during the year. Five physicians received licenses by recognition of their Canadian or foreign credentials in four states. One each was licensed in Arizona, New Hampshire and New York on the basis

of a license from Great Britain, Germany and Austria respectively, while North Carolina registered 2. 1 on the basis of a license from the Dominion of Canada and the other of a Nova Scotia license. Two were admitted to private practice in the Virgin Islands. Twenty retired officers of the government services secured licenses without written examinations in five states, 12 in California, 3 in Kentucky, 1 in North Dakota, 3 in Virginia and 1 in Wisconsin.

Not included in the table were 13 osteopaths licensed by medical examining boards in six states and the District of Columbia, namely, Indiana, New Hampshire, Oregon, Texas, Wisconsin and Wyoming.

There were registered in four states 6 physicians who presented credentials from the territories and possessions, namely, 3 in California and 1 in Texas with credentials from Hawaii and 1 each in New York

and Washington with credentials from Puerto Rico and Alaska respectively. Diplomates of the National Board of Medical Examiners were licensed in forty-two states and Hawaii.

Fifty-seven licentiates of New York secured licenses to continue practice in New Jersey. Similarly, 33 physicians who were licensed in Illinois were registered in California. Less than 10 of the licentiates of Alabama, Arizona, Delaware, Florida, Idaho, Massachusetts, Montana, Nevada, New Hampshire, New Mexico, North Dakota, Rhode Island, South Dakota and Utah were endorsed in other states.

A total of 2,445 physicians secured licenses by endorsement of their credentials in 1942. The physicians so licensed, and in addition 13 osteopaths registered by medical examining boards, are recorded by school of graduation and state or territory where licensed in table 15. All of the four-year medical schools in the United States were represented as well as eight in Canada, thirty-six faculties of medicine and one licensing corporation of other countries, one unapproved medical school, forty-four medical schools now extinct and several osteopathic schools. The largest number of graduates of any one school so licensed was from Harvard Medical School, who were registered in twenty-five states and Hawaii. Tufts College Medi-

TABLE 17—*Licentiate Representing Additions to the Medical Profession 1933-1942*

1940	5,241	470	5,711
1941	5,241	470	5,711
1942	5,241	470	5,711
Total	41,002	3,703	44,705

cal School had 83 of its graduates licensed by this method in twenty states. Graduates of foreign faculties of medicine numbered 85 and were registered in twenty states on the basis of a license issued elsewhere in the United States. One hundred and fifty-three graduates of medical schools now extinct migrated to thirty-six states and Alaska, 29 going to California. Fourteen graduates of unapproved schools were registered in seven states.

Of the 2,458 candidates licensed by reciprocity and endorsement, 2,158 were graduates of existing approved medical schools in the United States, 48 of eight approved schools in Canada, 85 were graduates of foreign faculties of medicine, 153 of institutions now extinct and 14 from unapproved and osteopathic schools.

LICENTIATES REPRESENTING ADDITIONS TO THE MEDICAL PROFESSION

The number of physicians who received their first license to practice medicine and surgery in 1942, and therefore represent additions to the medical profession, are recorded in table 16. Figures represent candidates examined in 1942 and immediately licensed, also those examined in previous years whose licenses were withheld for lack of internship, citizenship and other technicalities and issued in 1942, and those without a state license who were during the year certified on the basis of the examination of the National Board of Medical Examiners, government services, Canadian and foreign credentials. The majority represent recent graduates.

There were 5,981 additions to the medical profession in 1942. It is not known how many of these are at present in civilian practice. The annual number of deaths reported to the American Medical Association in 1942 was 3,353. It would appear therefore, that the physician population in the United States last year was increased by 2,628. The greatest number in any one state, 1,147, was added in New York. More than

1,000 were registered on foreign credentials and to a large extent diplomates of the National Board of Medical Examiners.

Comparative figures for seven years and 1942 are given in table 17. Last year the number of physicians representing additions to the medical profession increased 269 over the previous year but the number so registered was 443 fewer than in 1937, in which

300 received their first licenses in California, Illinois and Pennsylvania. In thirteen states between 100 and 299 physicians received initial licenses. Thirty states, the District of Columbia and Hawaii increased their physician population by fewer than 100. Nevada granted no original licenses during 1942.

Of the licentiatees constituting additions to the medical profession last year, 5,529 secured their licenses by examination and 452 by endorsement of credentials. Those licensed by endorsement consisted of a few reg-

istered on foreign credentials and to a large extent diplomates of the National Board of Medical Examiners.

Altogether in eight years 47,995 physicians received original licenses, 44,002 after written examination and 3,993 by endorsement of credentials. In the same period 72,107 medical licenses have been issued, 50,027 by examination and 22,080 by endorsement of credentials. Of these, 24,112 were previously licensed.

In table 18 data pertaining to those securing their first medical license are tabulated for each of the medi-

cal schools in the United States. Notable among the schools having a considerable number of graduates receiving their first license were 188 graduates of Tulane University School of Medicine and 170 graduates of the University of Texas Medical Branch. Ten other schools contributed more than 100. The medical schools of Boston University, the University of Vermont, Albany Medical College and the Woman's Medical College of Pennsylvania contributed fewer than 30. McGill University Faculty of Medicine added 21 of its graduates to the medical profession of the United States.

From the United States schools there were added to the profession 4811. Canadian schools 54, foreign faculties of medicine 835, medical schools no longer in existence 189 and unapproved schools 92. Rush Medical College, which ceased to function with the graduating class of 1942, is represented among the extinct medical schools, and the greater number of the 189 represented are graduates of Rush Medical College.

Table 19 records increases in the physician population grouped in nine geographic divisions. The largest number, 1696 was added in the Middle Atlantic states. The East North Central group had a total of 1,061, the West South Central 693, the South Atlantic 638, the West North Central 558, the Pacific states 509, the New England group 403, the East South Central 313 and the Mountain states 98. Twelve were added to the medical profession by licensure in Hawaii.

There were 5529 graduates of all schools added to the medical profession in 1942 by examination for licensure and 452 by reciprocity or endorsement, a total of 5981. The number of living physicians in the United States at the time the American Medical Directory was published in 1942 was 180,496.

ACCELERATION OF MEDICAL COURSES

As a war emergency the medical schools of the country, with three exceptions, have adopted an accelerated program which provides for the utilization of the long summer vacation as a teaching period, and by continuing the schedule throughout the calendar year the four year medical course is completed in three years. The medical practice acts in a number of states, however, preclude licensure of applicants who pursue medical training under the accelerated plan. An analysis of the medical licensure laws of all the states was made by the Bureau of Legal Medicine and Legislation of the American Medical Association, which prompted the Federation of State Medical Boards of the United States, in cooperation with the Bureau, to present the results of its survey to the medical examining boards of the respective states. Letters were written to those states in which amendatory legislation was considered necessary in order that candidates following an accelerated program of medical education might qualify for licensure. There were nine such states: Georgia, Illinois, Kansas, Maryland, Michigan, Nebraska, New Jersey, South Carolina and Virginia. The legislature of Virginia was in session in 1942 and a bill was passed to remedy the situation in that state. The legislatures of the other eight states are meeting in 1943. Of the states in which a legislative amendment was necessary, Kansas, Maryland, Michigan, New Jersey and South Carolina have already completed legislative action so that graduates after accelerated courses, may obtain

licensure. In Nebraska corrective legislation is pending. No legislation has to date, been introduced in Georgia or Illinois. The licensing board of Georgia has informed the office of the Council on Medical Edu-

and Hospitals that requirements in the state do not prohibit licensure of physicians who have completed their studies under an accelerated program.

ACCELERATION OF PREMEDICAL COURSES

The minimum requirement for admission to approved medical schools since 1918 has been two years of college training, and since 1938 three years has been recommended. With the exception of California, Con-

neent, Nebraska and New Mexico (table 20) the state licensing boards, by statute in the majority of instances, require that an applicant for licensure must present evidence of having completed two years of college

In November 1942 the Council on Medical Education and Hospitals recommended that for the duration of the

TABLE 20—Requirements of Preliminary Training by Medical Licensing Boards

war premedical education including satisfactory courses in physics biology and chemistry, including organic chemistry be included within two calendar years of instruction. Such a program is being adopted by practically all the medical schools of the country.

The collegiate training programs now being formulated by the Army and Navy, however, provide for an acceleration of premedical education which may present licensure problems in the future, and additional legislation will be necessary in some states in order that a physician who has had less than the two year premedical requirement may obtain licensure.

REQUIRED HOSPITAL INTERNSHIPS

In tables 21 and 22 are listed the medical schools and licensing boards now requiring internships for the M.D. degree and licensure respectively.

The medical licensing boards of twenty-two states, the District of Columbia, Alaska, Hawaii and Puerto

TABLE 21—Internship Required by Medical Licensing Boards of All Candidates

Michigan	Puerto Rico	

Some states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants.

* Internship requirement shortened to nine months for the duration of the war.

Rico require that all applicants for licensure serve a hospital internship. Here again the accelerated program has introduced a problem for the licensing boards. With the graduation from medical schools at nine month intervals, hospitals are accepting interns on a twelve month basis, but to avoid overlapping or to be of some aid to hospitals unable to secure interns, some hospitals will permit interns to complete the one year internship allowed by military authorities in another civilian or

government hospital. In some instances this is being done independently and without affiliation with the other hospitals. In some ten states the medical practice acts require that an applicant must have completed an internship of at least twelve months. Replies to a recent inquiry addressed to the respective licensing boards of those states that require an internship as a prerequisite for licensure, regarding the acceptability of a year's internship served in two independent hospitals, indicate that such a service would be acceptable for licensure in the majority of these states, Montana, New Hampshire, Washington and Wyoming, however, replied that the acceptability of an internship thus served would rest with the discretionary powers of the board. Illinois replied that it would not accept an internship served in this fashion, while Oklahoma responded that the matter had been referred to the attorney general for an opinion.

Legislation introduced in Delaware and Pennsylvania to reduce the required period of internship from twelve months to nine months has been enacted into law.

Some states permit an intern to take the medical licensing examination before completion of his internship but withhold issuance of the license.

Seven medical schools in the United States and four in Canada require completion of the internship before awarding the M.D. degree. Several medical schools will accept research or clinical work in lieu of hospital

service. At the University of Illinois College of Medicine the internship requirement was waived in 1941 because of the national emergency. With the institution of the accelerated curriculum at the University of California Medical School the requirement for an internship was discontinued for the seniors enrolled for the session 1941-1942. Wayne University College of Medicine granted degrees in March of this year to the seniors accelerating the medical course in 1942, thus waiving the requirement of an internship. However, the seniors who were in session during 1941-1942 are at present interning and will receive their degrees in June 1943. Marquette University School of Medicine, on the other hand, dropped the requirement of internship in August 1942, thus permitting the seniors who completed their work in June of that year to secure their degrees in December 1942.

The University of Minnesota Medical School in 1915 was the first school to adopt the internship as a basis for the M.D. degree, and the first state exacting this requirement was Pennsylvania in 1914. Several states in addition require graduates of medical schools abroad and reciprocity or endorsement applicants to have completed an internship. Since 1936 nine schools have dropped the internship requirement.

LICENSURE FOR THE RELOCATED PHYSICIAN

Removal of physicians from civilian practice has resulted in a shortage of physicians in critical areas. To assist the physician attempting to relocate in such

areas or in industrial sections of the country, it has been suggested that licensing boards modify their reciprocal and endorsement relationships and expedite licensure procedures. In eleven states namely

Arizona	Georgia	Rhode Island
Arkansas	Louisiana	South Carolina
Delaware	Mississippi	Washington
Florida	Nevada	

the medical practice acts provide for the issuance of temporary permits or certificates to practice medicine valid until the next ensuing examination. Whether or not the enactment of basic science laws in some of these states will interfere with the issuance of temporary permits is a matter about which no final opinion can be ventured.

In addition to the states named the New Jersey medical practice act exempts from its requirements a lawfully qualified physician and surgeon of another state taking charge temporarily of the practice of a lawfully qualified physician of New Jersey during his absence from the state, on written request to the board of medical examiners for permission to do so. Pending legislation provides that such permission may be granted for a period of not less than two weeks nor more than four months and that the board of medical examiners, at its discretion may extend such permission for further periods of two weeks to four months but not to exceed

* Biennial registration

* After July 1 1943

in the aggregate one year. In two states, Delaware and Nevada legislation has been enacted providing for the issuance of temporary permits or licenses, valid generally for the duration of the emergency. In Pennsylvania and Maine similar legislation is pending. In Kansas and Vermont the proposals to authorize the issuance of temporary permits or licenses were defeated this year.

ANNUAL REGISTRATION

Twenty-seven states, the District of Columbia, Alaska and Hawaii, as shown in table 23, require that all applicants register annually. Some of these states require such registration whether or not physicians reside in the state. The fee is generally \$2. A bill to establish annual registration in Wisconsin is pending.

Legislation to relieve physicians in military service from the necessity of complying with the annual registration laws has been enacted in Kansas, Minnesota, New York, Utah, Washington and West Virginia. Similar legislation failed of enactment in Idaho and has been received unfavorably by legislative committees in Colorado and Missouri. Wisconsin legislation pending exempts physicians in military service.

The licensing boards of all the states named in table 23, with the exception of Arizona, Colorado, Florida and Wyoming, have indicated that the requirement of annual registration has been waived for physicians in the armed services.

CANDIDATES EXAMINED

In table 24 are tabulated the number of candidates examined in the various states, territories and possessions in the five year period from 1938 to 1942. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five year period and the percentage of candidates who failed are also given. In New York 5 017 were tested and passed, 2 150 in Illinois, 2 140 in Pennsylvania and 2 040 in California. More than 1 000 were successful also in

Massachusetts, Michigan, Minnesota, Ohio and Texas. The smallest number, 6, passed the examinations in New Mexico.

The percentage of failures in all states in the period has increased from 11.7 in 1938 to 15.4 in 1942. However the percentage of failures last year was lower than in the three previous years when 19.6, 20.6 and 16.3 respectively failed.

The percentage of candidates who failed in examinations in the past five years is given in the last column for each state. The greatest percentage of failures, 50.7, occurred in Massachusetts. The high percentage in this state is due to the fact that by law the licensing board is required to admit to its examinations the graduates of unapproved schools, many of whom repeatedly fail. New York had a failure percentage of 43.0, occa-

sioned in large part by the admittance to examination of a considerable number of graduates of foreign faculties of medicine, who likewise repeatedly fail. On the other hand twenty-nine states failed less than 5 per cent. In sixteen of these states the percentage

TABLE 25—Registration, 1901-1942

1939	7,180	6,076	15.4	2,418	8,774

of failures was less than 1. In five years six states, Arkansas, North Carolina, Oklahoma, Oregon, South Dakota and Utah, had no failures.

A total of 37,861 were examined from 1938 to 1942, inclusive of whom 31,507 passed and 6,354, 16.8 per cent, failed.

These figures represent examinations given and not individuals. A candidate who fails more than once in a given year is counted as only one failure, but should he fail in one of the succeeding years he is counted in that year. The same is true of successful candidates. This table is merely a compilation of the figures computed annually and grouped for comparison. It gives a fair approximation of the number of physicians added to the profession in five years by means of written examination. On page 101 is a compilation giving exact figures for the period 1935 to 1942.

REGISTRATION, 1904-1942

The study of totals and percentages for thirty-nine years (1904-1942) will be found in table 25. This table includes figures for each year covering the number examined and passed, the percentage failed, the number registered by reciprocity or endorsement and the total registered. There was no definite increase or decrease in the number registered from 1907 to 1933, but in 1936 there was a very noticeable increase which also appeared during the following three years, while since 1938 the number registered has decreased. However, the number licensed without examination since 1904 has been increasing as a result of the wider recognition of reciprocal relations and the acceptance of the certificate of the National Board of Medical Examiners.

The decrease of more than 1,200 in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life in World War I. However, in the following year the number registered was 2,389 greater than in 1918.

A similar situation prevailed in 1941, when 337 fewer were registered although this decrease was due in part to the fewer graduates of European schools registered as compared with several previous years. Again in 1942 there was a decrease of 283, which may be the result of recent graduates entering military service without first securing a state license.

The greatest number registered in thirty-nine years was 9,807 in 1937, of whom 6,604 passed licensing tests and 3,203 were endorsed by registration.

The percentage of failures annually dropped from 20.8 in 1905, when a great many proprietary medical schools were functioning, to 5.7 in 1930. Improvements in the standards of medical education have resulted in a decrease of failures in licensing examinations. With the migration of physicians to this country beginning in 1936 and the resultant licensure difficulties, the failures began to rise until they reached a peak of 20.7 per cent in 1940. The percentage dropped 1 in 1941 for the country as a whole and 4.3 in 1942. The rise of failure percentages in recent years has been due in large part to the inability of graduates of unapproved schools and of foreign faculties of medicine to obtain licensure successfully without failure.

While these figures represent those registered in the years given, they do not represent actual additions to the medical profession.

GRADUATES OF APPROVED MEDICAL SCHOOLS AND OTHERS REGISTERED, 1922-1942

The educational fitness of the individuals registered in twenty-one years is recorded in table 26. In the computation of these figures, schools rated as class A and B by the Council on Medical Education and Hos-

TABLE 26—Graduates of Approved Medical Schools and Others Registered, 1922-1942

1942	7,247	84.9	1,287	15.1	8,534
Totals	145,575	88.2	19,452	11.8	165,027

pitals of the American Medical Association since 1907 are classified as approved. In the column "Others" are included individuals who graduated prior to 1907, when the first classification of schools was made, graduates of foreign faculties of medicine, class C graduates, osteopaths given recognition by medical licensing boards and graduates of schools not approved by the Council.

In 1928 the classification A B and C by the Council was discontinued and a list of approved medical schools has since been maintained

Of the 8,534 registered by all methods in 1942, 849 per cent represent graduates of approved schools and 1 287, 15 1 per cent, the group designated as others

In twenty-one years a total of 165,027 were registered, including 145 575 approved graduates (88 2 per

cent) and 19,452 others (11 8 per cent) The improved standards in medical education are again evident by a study of these totals and the percentages representing approved graduates

The number of graduates of approved schools in the period shown has annually represented more than 80 per cent of those registered Until the influx of foreign graduates in 1936 the number in the second group has always been well below 1,000

Of the 8,534 registered in 1942, 4,974 graduates of approved medical schools of the United States and Canada were licensed by examination and 2 273 were endorsed By examination 217 unapproved graduates and 885 foreign graduates were registered Likewise, among those registered by endorsement there were 21 graduates of unapproved schools and 164 foreign graduates

New York registered 632 graduates of approved schools of a total of 1,330 This state licensed the largest number with foreign credentials 698 Only graduates of approved schools in the United States and Canada were registered in Delaware, Florida, Idaho, Louisiana, Minnesota, New Mexico, North Dakota, Rhode Island, Utah and West Virginia

GRADUATES OF UNAPPROVED MEDICAL SCHOOLS REGISTERED 1937-1942

Graduates of institutions which do not meet the educational standards outlined by the House of Delegates of the American Medical Association and enforced by the Council on Medical Education and Hospitals were registered in twenty states, Alaska, Hawaii and Puerto Rico in the last six years The number so registered will be found in table 27 In the six years shown 1 113 were registered 1 014 by examination and 99 by reciprocity or endorsement In 1942, 157 received licenses after examination in three states—namely Illinois, Massachusetts and Mississippi and

1 by endorsement in Indiana Two states (Massachusetts and Illinois) registered all but 2 of the candidates

GRADUATES OF SCHOOLS OF OSTEOPATHY REGISTERED BY MEDICAL EXAMINING BOARDS, 1937-1942

The number of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by the medical examining boards of twelve states for a six year period are given in table 28 There have been 759 such individuals registered since 1937, 588 by examination and 171 by endorsement

In 1942 ten states registered 60 by examination and 13 by recognition of their credentials a total of 73 Massachusetts and Texas issued 31 of the 73 so licensed In six years Texas registered 237 New Jersey 233 and Massachusetts 104, a total of 574

PHYSICIANS EXAMINED ON THE BASIS OF CREDENTIALS OBTAINED IN COUNTRIES OTHER THAN THE UNITED STATES AND CANADA

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada It therefore has no evidence on which to base a rating For several years the Council was in a position to verify the claims of physicians presenting such credentials, but for several years this has not been possible and on the licensing boards themselves rests the responsibility of both verifying and evaluating the credentials presented by these graduates In the 1942 edition of the American Medical Directory a symbol in the biographic data indicates that the information given is the licensing board's record of the credential accepted as meeting the educational qualification for licensure The absence of the symbol indicates that official verification is on file in the office of the Council

Nineteen states reported that holders of credentials obtained in countries other than the United States and Canada are not eligible for licensure The requirements for candidates for medical licensure in the United States, Alaska, Hawaii and Puerto Rico holding such credentials are given in table 29 Eighteen states, Alaska, Hawaii and Puerto Rico require full citizenship and

* Refer to chart of "Reciprocity and Endorsement Policies" for further data.

- 1 Certificate of National Board of Medical Examiners and licensure in country in which school of graduation is located
- 2 Internship or one year in medical school in United States
- 3 Certificate of National Board of Medical Examiners
- 4 For graduates of last five years, if more than five years \$50
- 5 Residence of one year in Delaware
- 6 If similar privileges are accorded licensees of District of Columbia by licensing agency of jurisdiction from which applicant comes
- 7 Senior year in class A medical colleges after July 1, 1936 Switzerland
- 8 Graduates of European medical colleges after July 1, 1936 Switzerland and excepted, shall not be eligible for licensure. Graduates prior to this date may be accepted for the regular written and clinical examination after completing rotating internships in approved hospitals in Illinois
- 9 Enemy aliens not accepted
- 10 Application must be filed six months prior to date of examination
- 11 Licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States
- 12 Diplomates of National Board of Medical Examiners eligible
- 13 License to practice medicine and surgery in the country in which the school of graduation is located
- 14 Internship and one year graduate work
- 15 Diplomates of the National Board of Medical Examiners exempt from special requirements
- 16 Internship and graduate work
- 17 Internship completed in foreign countries after July 1, 1934 not acceptable
- 18 Rotating internship in approved hospital in the United States or completion of senior year in class A medical school in the United States
- 19 These requirements apply also to graduates of Canadian schools
- 20 Graduates from foreign medical colleges accepted if they present also a diploma from an approved medical school in the United States
- 21 Provided standard was the same as California on the same date
- 22 Degree from an American medical college acceptable to the Medical Council of Delaware required
- 23 Diplomates of the National Board of Medical Examiners accepted
- 24 Very limited number contracting to practice in rural districts may be accepted
- 25 Effective July 1, 1943
- 26 Homeopathic board requires one year internship in homeopathic hospital in the United States

States hospital approved for intern training. In five states there is a requirement of a senior year's work in an approved medical school in the United States. Other prerequisites are given in footnotes beneath the table.

Table 30 presents figures relating to physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards in the United States and Hawaii. The figures represent both American and foreign born physicians educated abroad. Ninety-nine faculties of medicine and three licensing corporations of twenty-two European and four other countries and the Philippines were represented. There were 1,630 examined by twenty-four states and Hawaii, of whom 890 passed and 740, 45.4 per cent, failed. Graduates of the University of Vienna represented the largest group, 397, who were examined in thirteen states with a failure percentage of 45.1. Nine states examined 111 graduates of the University of Berlin, of whom 50.5 per cent failed. Graduates of all other schools were examined in fewer than eleven states. The greatest number examined by any one state was 1,263 in New York, of whom 670

TABLE 31—Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930-1942

Year	Number Examined	Passed	Percentage Failed
1930	167	92	44.9
1931	158	91	42.4
1932	182	96	47.3
1933	200	129	35.5
1934	235	170	40.2
1935	457	308	30.7
1936	558	352	35.0
1937	920	637	30.8
1938	1,164	716	38.5
1939	1,691	839	50.4
1940	2,088	948	54.7
1941	1,717	698	59.2
1942	1,630	890	45.4
Totals	11,227	5,991	46.6

passed and 593 (47.0 per cent) failed. No other state examined more than 65 such candidates. Fewer than 5 were tested by thirteen states and Hawaii. The percentage of failures of graduates of seventy-seven of the schools was more than 25.

Table 31 records the number of graduates of faculties of medicine abroad examined for medical licensure in the United States in thirteen years, 1930-1942 inclusive. All together 11,227 were examined, of whom 5,991 passed and 42.6 per cent failed. The greatest number, 2,088, was examined in 1940, when 54.7 per cent failed. The number licensed in twelve years increased from 92 in 1930 to 948 in 1940. In 1942, 58 fewer than in 1940 were registered. The highest percentage of failures occurred in 1941, 59.2 per cent. At no time during this thirteen year period did fewer than 30.7 per cent fail.

In table 32 are assembled figures showing for the five year period 1937-1942 the number of graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. Included also is a tabulation for 1942. The largest group from any one school examined in the five year period was 1,739 from the University of Vienna, of whom 49.6 per cent failed. There were 741 from the University of Berlin, of whom 49 per cent failed. Large numbers also were examined who presented credentials from the universities of Prague, Paris, Freiburg, Frankfurt-am-Main, Wurzburg, Munich,

Bonn, Heidelberg, Breslau, Budapest, Bologna, Naples, Rome, Basel, Bern, Zurich, Geneva and Lausanne. Also in the five year period there were 315 who presented in lieu of the M.D. degree the triple qualification certificate of Scotland. These individuals secured their education in the so-called extramural schools of Scotland.

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

Examining and certifying boards have been established in fifteen specialties namely anesthesiology, dermatology and syphilology, internal medicine, neurologic surgery, obstetrics and gynecology, ophthalmology, orthopedic surgery, otolaryngology, pathology, pediatrics, plastic surgery, psychiatry and neurology, radiology, surgery and urology. On authorization of the House of Delegates of the American Medical Association, the Council on Medical Education and Hospi-

Examining Boards in the Medical Specialties

Key No. A B	Name of Board	Year of Incorporation	Certificates Awarded	
			Total Issued to March 1, 1942	March 1, 1943
1	American Board of Pediatrics	1913	1,741	1,959

14	American Board of Plastic Surgery	1917	127	157
15	American Board of Neurological Surgery	1910	107	138
Totals			19,561	21,733

Certification in the subspecialties. By the American Board of Internal Medicine: Allergy 68, cardiovascular disease 260, gastroenterology 122, tuberculosis 119, total 569. By the American Board of Surgery: Proctology 61. Total certified in the subspecialties 630.

tals in 1934 formulated standards governing specialty boards, and these fifteen boards are fully approved by the Council. In addition to regulations relating to the organization and operation of specialty boards, The Essentials of Approved Examining Boards in Specialties contain also the minimum qualifications deemed necessary for certification as a specialist. The latter include graduation from an approved medical school, an internship in a hospital approved by the Council and a period of specialized training in a selected specialty.

The American Board of Internal Medicine by special examination certifies specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis. Similarly the American Board of Surgery certifies specialists in proctology.

During the period of the war the training of young men to meet the requirements of the specialty boards will be greatly curtailed since provision for military deferment beyond the internship will be granted to comparatively few. However, the specialty boards have not lowered their requirements because of war conditions, but the majority of them will grant some credit for military service which will compensate in

part for the interruption of planned programs of graduate training by the call of physicians to active service in the armed forces. The policies adopted by the specialty boards vary from the granting of an indefinite amount of credit, to be determined by the evaluation of the experience of individual applicants, to full credit for work done in the surgical division of a regularly constituted army or naval hospital. The Office of the Surgeon General of the Army has announced that men in service eligible for board examinations may request orders to detached duty for the purpose of taking these examinations.

The number of certificates awarded prior to March 1, 1942 and those certified from that date to March 1, 1943, respectively, appear in the accompanying tabulation. On March 1, 1942 there were 19,561 physicians certified by the fifteen specialty boards and, in the following year, 21,732, a total of 21,733 excluding the subspecialties.

In the subspecialties 630 have been registered, namely allergy 68, cardiovascular disease 260, gastroenterology 122, proctology 61 and tuberculosis 119.

The greatest number certified by any one board was the 3,570 physicians certified in otolaryngology since the organization of the board in 1924. In internal medicine 2,905 have been certified and in surgery 2,144. The board in ophthalmology, organized in 1917 and the oldest board in existence, has to date certified 2,198 physicians.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Seventeen states and the District of Columbia have adopted by legislative action basic science requirements underlying the practice of the healing art. These acts provide for certification by a board of examiners in the basic sciences as a prerequisite to eligibility for a license to practice any branch of the healing art, whether the license is to be issued after written examination or on the basis of endorsement of credentials or reciprocity. Connecticut and Wisconsin in 1925 were the first states to enact laws. Very few legislatures were in session in 1942 and no basic science law was enacted during the year. A referendum to create such a law in California in 1942 was defeated. At the recent session of the Tennessee legislature, however, a basic science law was passed which becomes operative during the current year. While the laws of some states include reciprocal agreements, the certificate is obtainable only after examination in the majority of states.

In 1942 basic science boards were in operation in Arizona, Arkansas, Colorado, Connecticut, Florida, Iowa, Michigan, Minnesota, Nebraska, New Mexico, Oklahoma, Oregon, Rhode Island, South Dakota, Washington, Wisconsin and the District of Columbia. These states, together with the year of enactment of the basic science law, are recorded in table 1.

Shown in table 2 are the subjects in which examinations are conducted by the respective states and the District of Columbia. These subjects are specified by statute. The examining boards are not authorized to add any subjects or to refrain from giving examination in any subjects specified in the statute. Tennessee is included in this table. All boards examine in anatomy, pathology and physiology, sixteen examine applicants in chemistry, fourteen in bacteriology, eight in hygiene, two in diagnosis and one in public health.

Statistics presented in the succeeding paragraphs in this section cover the year 1942 and therefore omit reference to the state of Tennessee, which enacted its basic science law in 1943. The data included in the tabulations have been received from the officials of the respective boards. The figures given are presented

TABLE 1—States Having Basic Science Laws and Year of Enactment

Arizona	1936	Nebraska	1927
Arkansas	1929	New Mexico	1911
Colorado	1937	Oklahoma	1937
Connecticut	1925	Oregon	1933

Florida	1939	South Dakota	1939
Iowa	1935	Tennessee	1943
Michigan	1937	Washington	1927
Minnesota	1927	Wisconsin	1925

in four groups namely physicians or medical students, osteopaths, chiropractors and unclassified applicants. In applying for a basic science certificate it is not a requirement in most of the states to mention the school of practice. By checking the biographic and medical student records of the American Medical Association and various directories, it has been possible to determine the profession of the majority of candidates thus permitting the classification of the number of applicants into the three groups. For some it was not possible to determine the profession represented, and they are tabulated in the unclassified group. In this group it is believed are represented osteopaths, chiropractors, naturopaths and doctors of dentistry.

The basic science boards of seventeen states named in table 3 examined in 1942 a total of 2,235 candidates. Of this number, 1,725 were physicians or medical students, 258 were osteopaths, 24 chiropractors and 215 were placed in the unclassified group. Of all applicants, 22.8 per cent failed. Of the physicians or medical students examined, 14.4 per cent failed, osteopaths 44.6 per cent, chiropractors 62.5 per cent and unclassified 54.9 per cent. Among those who passed, there were

TABLE 2—Subjects

Washington	+	+	+		+	+	+
Wisconsin	+			+	+	+	+

1,476 physicians or medical students, 143 osteopaths, 9 chiropractors and 97 unclassified. The basic science board of Iowa examined the greatest number of applicants, 436, representing 129 physicians and medical students, 108 osteopaths, 5 chiropractors and 104 unclassified. Of those examined in Iowa, 40.4 failed. The next largest number, 266, were examined in Minnesota with 18.8 failures. The second greatest number of failures on the other hand was in Michigan, 36

per cent. The District of Columbia reported no failures for the year, examining 15 physicians and 1 osteopath.

Osteopaths were examined in Colorado, Connecticut, the District of Columbia, Florida, Iowa, Michigan, Minnesota, New Mexico, Oregon, Rhode Island, Washington and Wisconsin. Chiropractors appeared for examination in six states—Connecticut, Florida, Iowa, Oklahoma, Washington and Wisconsin.

It is the policy of the Arizona board of examiners in the basic sciences to omit the names of applicants who fail examinations, and the law does not require the board to record the professional school of graduation of the examinees. Failures for this state, therefore, are recorded only in the total column.

Ten states issued 304 certificates by reciprocity, endorsement or waiver, and the boards of all states granted 1,725 certificates after examination. The number of successful applicants (2,029) registered by

* School of practice undeterminable since names of failures not supplied.

examination reciprocity, endorsement or waiver are recorded in table 4. Among the successful candidates were 1,689 physicians, 205 osteopaths, 14 chiropractors and 121 unclassified individuals. Minnesota certified 74 without examination, the greatest number, of whom 60 were physicians, 3 osteopaths and 11 unclassified. Arizona, Florida and Washington have no reciprocal relations. None were certified without examination in Connecticut, New Mexico, Oklahoma and Rhode Island.

Osteopaths were registered in all states except Arizona, Arkansas, Nebraska and Oklahoma while chiropractors were registered in Connecticut, Florida, Iowa, Michigan, South Dakota, Washington and Wisconsin. Altogether 2,029 candidates received basic science certificates in 1942 in seventeen states ranging from 16 in New Mexico to 290 in Minnesota.

In table 5 is tabulated the number of candidates examined and certified by basic science boards in sixteen years, 1927 to 1942 inclusive. In 1927 when five boards were functioning there were 646 physicians examined of whom 9.3 per cent failed and 59 other practitioners of whom 47.5 per cent failed. In 1942 by comparison 1,725 physicians were examined of

whom 14.4 per cent failed, and 497 other practitioners, with 49.9 per cent failures.

In the sixteen year period there were 15,307 physicians or medical students examined of whom 13,437 were successful in their examinations, while in the

same period 2,283 other practitioners took the test and 1,115 were successful. Of the physicians examined in this period 12.2 per cent failed to pass, while 51.2 per cent of the other practitioners failed to pass. Since 1927, 3,076 physicians and 571 other practitioners have been certified without examination.

All together during this sixteen year period 18,199 certificates have been granted by basic science boards of whom 16,513 were physicians and medical students, 1,686 were other practitioners.

Basic science legislation has been enacted in an attempt to provide a means of insuring that all applicants seeking licensure to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art. From the statistics here presented it would appear that the enforcement of such laws affects mostly the group classified as other practitioners.

NATIONAL BOARD OF MEDICAL EXAMINERS

The certificate of the National Board of Medical Examiners is accepted as an adequate qualification for a medical license by the licensing authorities of all but four states, the District of Columbia, the territories of Alaska, Hawaii and Puerto Rico and the Canal Zone. The provisions of the medical practice laws or state board regulations of a few states are such that diplomates of the National Board are required to take an oral examination in Connecticut, Illinois, Maine, Montana, Rhode Island and Wyoming. A brief supplemental written examination is required in Michigan. Pennsylvania requires a rotating internship. The states, territories and possessions which will endorse certificates of the National Board of Medical Examiners are recorded in table 1.

TABLE 1—States Endorsing Certificates of National Board of Medical Examiners

Alabama	Illinois	Nebraska	Rhode Island

The examinations of the National Board are accepted in lieu of the examinations in these subjects given by the boards of examiners in the basic sciences of Connecticut, Iowa, Minnesota, Nebraska and the District of Columbia.

In the following paragraphs data are presented for the twenty-fifth consecutive year regarding the examinations conducted and the issuance of certificates by the National Board of Medical Examiners. These statistics are based on official reports received periodically from the executive office of the National Board.

Graduates of approved medical schools in the United States and Canada are eligible for certification. Graduates of the university medical schools of Great Britain and Ireland are admitted to the examinations of the National Board provided these graduates have been licensed to practice in the country in which the school is located.

From October 1916 to Dec. 31, 1921 eleven examinations were held and 268 candidates were certified. The results of each examination during this period are given in table 2.

Since 1922 the examination has been divided into three separate parts, which must be taken and completed in the following sequence. Part I, a written examination in each of the six fundamental medical sciences, Part II, likewise a written examination in five major clinical subjects and Part III, a clinical and practical examination in six major clinical subjects and their component subjects or subdivisions. Examinations in Parts I and II were formerly held in February, June and September at approved medical schools, and the Part III examinations were held at times sufficiently frequent to accommodate all eligible candidates in twenty-three established centers throughout the United States. The usual schedule of examinations in Parts I and II has been changed to accord more nearly with the accelerated curriculum of the medical schools. Examinations during the present year have already been held in January and March. Another examination in these parts will be given in August and

the end of their second year in schools whose third year curriculums include courses in one or two subjects of this part. The examinations in the subject not yet completed are therefore postponed and may be taken at any examination period after the candidate has completed them in his medical school. A candidate not

again in the month of November. Special examinations in Part III will be held from time to time in centers having a sufficient number of candidates to warrant doing so.

Although there has been no change in any of the established regulations of the National Board because of the war emergency in matters pertaining to premedical education curriculum and internships the Board is prepared to abide by the recommendations of the Council on Medical Education and Hospitals of the American Medical Association and the wartime changes now in effect in the majority of approved medical schools.

The tables hereinafter presented enumerate the results of examinations in Parts I, II and III for each calendar year since 1922 including those who passed and failed examinations and those certified.

After completing successfully the first two years in an approved medical school the candidate is eligible for Part I. Candidates are required to take all six subjects of this part at a regular examination period unless entitled to take an incomplete examination or electing to take a divided examination. An incomplete examination is allowed candidates taking Part I at

Between 1916 and 1921 a total of 22 were examined of whom 22 passed and 0 per cent failed. Total certificate awarded up to and including 1916-1921.

A physician is eligible for Part II who has passed Part I and has completed successfully a four year medical course in an approved medical school.

Three examinations in Part I were held in 1942 and four in Part II. The results of these examinations together with totals for twenty-one years are included in tables 3 and 4. The figures cover the details of each examination given during a calendar year at 1

include some who failed and were reexamined during the same year and also some who passed Parts I and II in the same year. They therefore represent examinations conducted rather than individuals examined.

During the past year 1,865 examinations were given in Part I of which 1,204 candidates passed and 190,

102 per cent failed. In 1942 also 471 incomplete examinations in Part I were given. In 1942, 1,072 examinations were held in Part II. There were 1,031 successful examinees and 41, or 3.8 per cent, failures.

Since 1922 a total of 24,267 examinations have been given in Part I and 13,157 in Part II. During this period 15,425 candidates passed Part I and 12,081

passed Part II. In twenty-one years there have been 2,611 failures in Part I, 10.7 per cent, and 1,030 failures in Part II, 7.9 per cent. From 1922 to 1942 inclusive, 6,231 candidates took incomplete examinations in Part I and 46 in Part II.

A candidate is eligible for Part III who has passed Parts I and II, received the degree of Doctor of Medicine and has satisfactorily completed an internship of at least one year in a hospital approved by the Council

on Medical Education and Hospitals of the American Medical Association or by the Department of Hospital Service of the Canadian Medical Association or has served a year in an acceptable laboratory.

The results of examinations in Part III for the twenty-one year period 1922 to 1942 are given in table 5. In 1942, 1,053 were examined as compared with only twenty-two in 1922. This was the greatest number examined in any one year. Of those examined in 1942, 13, or 1.2 per cent, failed. In twenty-one years 10,268 were examined, of whom 9,864 were granted certificates and 404, 3.9 per cent, failed. Between 1916 and 1921, certificates were awarded 268 candidates. Since the inception of the board in 1916, 10,132 certificates have been awarded. Physicians who earned the certificate are designated Diplomates of the National Board and are privileged to use the designating initials D.N.B.

In table 6 are recorded the number of individuals examined during any one year. The classification of passed or failed in cases in which more than one examination has been taken in a given year was based

on the results of the last examination during the year in question. For example, if in 1942 a candidate passed Part I but later in 1942 failed Part II he is computed in the tabulation as having failed. On this basis figures computed indicate there were 3,607 who took at least one of the examinations of the National Board in 1942 as compared with 525 in 1922. A total of 44,095 individuals was examined in one or more of the examinations in the twenty-one years shown, of whom 34,657 passed, 5,910 took incomplete examinations and 3,528, 8 per cent, failed.

Physicians certified as Diplomates in 1942 numbered 1,040, representing graduates of fifty-three medical schools in the United States, one school now extinct, two in Canada and 50 graduates of faculties of medicine abroad. Table 7 records the number of Diplomates from each school certified last year.

Diplomates licensed to practice medicine on the basis of their credentials increased from two in 1917 to 702 in 1942, 7,572 having been so licensed since the National Board was formed. However, 10,132 have received the certificate of the Board. In 1942 Diplomates were licensed on the basis of their National Board certificate in forty-one states, the District of Columbia and Hawaii. The number so registered in each state is recorded in table 8.

SATURDAY, MAY 8, 1943

PROVISION OF MEDICAL SERVICE IN CRITICAL AREAS

At a meeting of the War Participation Committee of the American Medical Association with the directing board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians and with representatives of the United States Public Health Service in Washington on Dec 14, 1942, plans were presented whereby the United States Public Health Service could meet the need for medical services in critical areas. The War Participation Committee of the American Medical Association at that time recommended that state medical societies cooperate with the State Procurement and Assignment Service and with the state boards of registration and licensure in determining areas that lack medical services and in developing plans for medical services in such areas when the need arises. The Secretary of the American Medical Association, Dr. Olin West, was requested to inform the secretaries of all state medical associations of the action taken. The Board of Trustees endorsed the activities of the War Participation Committee in this regard. In the meantime various measures have been taken in different areas to meet critical situations and in others plans have been developed for the future. These are as follows:

1 In some communities, local medical groups and health agencies have endeavored to arrange conditions so that the remaining physicians may extend their services as far as possible. Additional nurses for home visits and bedside care when they can be secured are of great value in conserving the time and energy of physicians. Additional hospital beds, clinics and health centers when they can be obtained greatly relieve many situations.

2 In most instances in which there is a real shortage of medical care, it is necessary for the State Procurement and Assignment Service to undertake to find physicians who can be spared from some com-

munities within the state and persuade them to relocate in others where they are needed more.

3 When a sufficient number of physicians cannot be induced to relocate in needy communities at their own expense, it is recommended that the Public Health Service be enabled to defray costs of moving and transportation within prescribed limits and if necessary to pay a stipend for a period not to exceed three months to enable the physician to establish himself and acquire sufficient practice to provide his living expenses.

4 When a serious shortage of physicians still exists in spite of all efforts to extend medical services to those in dire need, it is recommended that the Public Health Service be enabled to assign physicians to assist in the medical care of the citizens of such areas under the following conditions:

- (a) That such assignments be made only on official request of the state and local agencies which are responsible for the provision of such service.
- (b) That Public Health Service physicians so assigned be attached to the state and local agencies charged with the responsibility of rendering medical services and that their activities be conducted in accordance with the laws of the state.

In order to determine areas in which there is a critical shortage of physicians and to ascertain what action may be needed, the Procurement and Assignment Service of the War Manpower Commission, with the assistance of the Public Health Service has initiated a plan for surveying areas reported to have a medical care shortage. These surveys are made jointly by the State Procurement and Assignment Service and the Public Health Service, with the cooperation of the state health department and the state medical and dental societies.

There seems to be general agreement on the view that a ratio of 1 physician to 1,500 people is deemed desirable as a national average. Since, however, it will not be possible to secure such a ratio in all places, the absolute minimum that should be allowed to exist in war industry and military areas is to be 1 physician for each 3,000 people. Moreover, there are desperate situations in some agricultural areas because most of the effective physicians have left communities to join the armed forces. In order to permit the United States Public Health Service to carry on this work the Surgeon General has estimated that some 59 physicians and 5 dentists will be needed to relieve existing and anticipated medical and dental care shortages in some forty-two areas. Thus far the United States Public Health Service has been requested to supply or to assist in supplying 13 physicians and 2 dentists or approximately one fourth of the determined need. It is recognized that this activity of the United States Public Health Service is one for the emergency and that a

is not contemplated that the service will be further extended either for the emergency or in the postwar period in the field of medical care. Certainly the medical profession, including the regularly organized state and county medical societies, will do its utmost to cooperate with governmental agencies in making certain that the people of our country, and particularly those who have been dislocated into military and industrial areas to meet war needs, are provided with medical care.

DURATION OF PREGNANCY

Recent regulation changes by which the classification of registrants is to be established under the Selective Service System provide for a distinction between (1) men with child (or children) with whom they maintain a family relationship in their homes, provided such status (child) was acquired prior to Dec 8, 1941, and (2) men with wives only or with child (or children) acquired after Dec 8, 1941. As a result of these provisions it will become necessary for local Selective Service boards to determine beyond reasonable doubt in certain borderline instances whether a child has been conceived before or after Dec 8, 1941 in order to classify the registrant correctly.

Many reports have a bearing on this problem. Wahl¹ studied a series of 9,000 women to determine the length of pregnancy. He found that the average duration of gestation was 285 days, which is contrary to commonly quoted figures of 280 days. As pointed out by Schwarz,² pregnancy actually begins the moment the female egg cell becomes fertilized and ends with the birth of the child. The time estimated as the length of pregnancy is difficult to determine on account of several variable factors: (1) the question of the time of ovulation, (2) the time of migration, (3) the lifetime of the egg and the spermatozoa, (4) the time of impregnation and (5) the time of implantation of the ovum.

The Hotellings,³ who analyzed over 2,000 obstetric cases at the Stanford University Clinic, came to the following conclusions: "The conclusion of the earlier writers that 280 days is the average duration of normal pregnancy, that is, when the very short and very long durations are excluded, is confirmed by our study. However, the standard deviation from this average, which other students have estimated to be from 8 to 10 days, we find to be 11 days. If the early births are included, the mean duration is shorter and the standard deviation greater. The mean duration from the date of coitus to birth is 271 days, the standard deviation being scarcely any less than when duration is counted from the beginning date of the last menstruation. The standard deviation also seems to be no less when duration is counted from the last day of the last menstrua-

tion, as in England and France. Accordingly, there is no perceptible gain in accuracy by reckoning even from a single coitus of known date, unless, of course, the menstruation date is unknown."

The longest possible period of gestation has not been legally defined in this country. French law recognizes the legitimacy of a child born 180 days after marriage and 300 days after the death of the husband, the German law 181 and 302 days respectively. In England in 1921 the legitimacy of a child born 331 days after the husband went to war was allowed. In the United States each case is decided on its own merits, since there is no law in this country or in England which defines the duration of gestation.

The problem is further complicated by the fact that there are no accurate criteria for ascertaining the degree of hypermaturity of newborn infants, even fully formed teeth are sometimes found in those born at term. It can only be said that the weight of the newborn child when evaluated against the size of the parents and parity of the mother can be highly suggestive.

For practical purposes the burden of proving any pregnancy lasting more than 280 days would seem to rest on the claimant. Under such circumstances the claimant would be charged with presenting overwhelming medical evidence of the prolonged nature of the gestation. Any child born after Sept 15, 1942 could therefore not be considered as having been conceived before Dec 8, 1941 in the absence of overwhelming evidence to the contrary.

THE DISTRIBUTION OF PHYSICIANS AND STATE LICENSING LAWS

A perfect distribution of physicians based exclusively on the distribution of population can perhaps be obtained only in a totalitarian state, although neither the Germans nor the Russians seem to have solved the problem. One may suspect that even then it would be satisfactory only to the dictatorial regime and probably not to the medical profession or to the population itself. The distribution of physicians in the United States before the war no doubt left much to be desired, the war itself has accentuated the problem. Withdrawal of large numbers of doctors for federal services, shifts of masses of people to new locations, difficulties of transportation of doctors and patients, and crowding of hospitals are some of the newer aspects of the situation. As a result, a number of areas of real medical scarcity have developed.

This problem of relocation encounters many difficulties, one of which is the legal restraints imposed by the various state licensing laws. The suggestion that a federal emergency license good in any state is the solution has met many obvious objections. The directing board of the Procurement and Assignment Service held a joint meeting with the Executive Committee of the Federation of State Medical Boards on Dec 10,

1 Wahl, F. A. *Deutsche med. Wchnschr.* 63:125 (Jan 22) 1937.

3 Quoted by Schwarz.²

1942 and agreed to certain principles, which have been communicated to the licensing bodies of each state. These include procedures for determining the need of relocations of physicians. As far as possible relocations are to be accomplished by utilizing physicians already licensed within each state. When help from outside the state is necessary, full advantage should be taken of existing provisions for reciprocity between states and for interstate endorsement. Whenever existing laws make these measures impossible, a change in the law permitting temporary licenses during the emergency may be enacted, and a draft of such a law to serve as a model was provided. This model law contains restrictions of the right to practice, as regards both time and place. Finally, arrangements have been made with the United States Public Health Service whereby, when other efforts have proved unsuccessful and certain conditions required by the restrictions placed on the United States Public Health Service are met, that service may aid in supplying doctors to meet the necessities of the situation.

Two principal objects are sought: first is the best distribution of our available resources of medical personnel and the health protection of the largest number of people; second is the doing of this in such a way as to preserve the rights and advantages that inhere in local self government. A breaking down of the right of each state to determine for itself the standards of medical licensure and practice within its borders cannot be contemplated with indifference, even under the plea of war necessity. It may distress the judicious that one state may allow practice by those who are improperly qualified or that another may exclude excellent men by peculiar requirements. A uniformly sound standard of eligibility, and general reciprocity, in regard to licensure is desirable. It seems wiser, however, to reach this desirable goal by the natural evolution of experience and education than to substitute federal control.

AMINOACRIDINE COMPOUNDS AS SURFACE ANTISEPTICS

No doubt the discovery that sulfonamide compounds act locally as antiseptics served to revive the almost extinguished interest in local antiseptics. Of the newer antiseptics, gramicidin and penicillin appear to possess a striking antiseptic action; the effect of propamidine in chronic wound infection was recently commented on in THE JOURNAL.¹ In a recent issue of the *British Medical Journal* Browning² calls attention anew to the flavines. As early as 1913 Browning and Gilmour

demonstrated that the action of the diaminoacridine compounds, in contrast to all other efficient antiseptics, is intensified rather than reduced when the medium contains serum. Toxic damage from acriflavine or proflavine absorbed from wounds has not occurred. True necrosis may occur at the site of injection of flavines into closed tissues if the flavines are used in high concentrations. Russell and Falconer³ showed that 1:1,000 solution of proflavine and 2:7 diaminoacridine in isotonic saline solution buffered at the pH of 6.2 were harmless when applied to rabbit's exposed brain tissue, while acriflavine 1:1,000 and euflavine 1:2,000 caused hemorrhage and necrosis.

Considerable disparity appears in the studies of various investigators on the inhibitory effect of acridine compounds on the phagocytic activity of the leukocytes. Successful results with acridine compounds have been obtained repeatedly in recent wounds of mice inoculated with streptococci. After intraperitoneal inoculation of virulent streptococci, one intraperitoneal injection of the antiseptic after an hour's interval saved the lives of 60 per cent of the animals. Browning therefore concludes that it is possible to destroy infection in a freshly infected wound by the use of an antiseptic. There is also convincing clinical evidence that the flavines can control established suppuration in wounds and that this may occur in instances in which drugs of the sulfonamide group have failed. Continued use of the flavines, however, leads to retardation of granulation and healing so that it may be advantageous to change to other treatment later.

In the same issue of the *British Medical Journal*⁴ the reason for the failure of acridine compounds in the past is said editorially to be explained by the wrong choice of compound and misapplication. Thus acriflavine, which has been most popular in the past, was recently demonstrated to be least satisfactory. Recent researches show proflavine to be the compound of choice as an efficient wound antiseptic, probably superior to the sulfonamides in the presence of gas gangrene. The introduction by Mitchell and Buttle⁵ of the use of proflavine in powder form in treatment of wounds did away with one of the drawbacks common to all acridines when applied as solutions, namely their affinity for fabrics, which interfered with their diffusion into the tissues of the wound. The scarcity of penicillin and certain limitations of the sulfonamides make it desirable to investigate further the possibilities of the acridine compounds, in particular proflavine.

Current Comment

STATE BOARD NUMBER

The exceeding importance of making available at the earliest possible moment the facts regarding medical licensure in the United States has made it necessary for *THE JOURNAL* to publish the State Board Number at this time although somewhat abbreviated. The restrictions on the use of paper made it simply impossible to include many of the large tables which are usually incorporated in this number. However, the facts here included provide practically all the essential information that is usually incorporated in the issue devoted particularly to the results of the state board examinations. The Council on Medical Education and Hospitals will make available in the form of a reprint the usual full report for those who are especially desirous of having the more detailed statistics.

MATERIALS USED FOR PHARMACEUTIC PURPOSES EXEMPTED

Under an order released by the Office of Price Administration on April 29, by-products of animal slaughtering operations used only for pharmaceutical or nonfood purposes were expressly exempted from the meats and fats rationing regulations. This order, effective May 5, excludes adrenal glands, bile, epididymides, lymph glands, ovaries, parathyroid glands, pineal glands, pituitary glands, placentas, prostate glands, salivary glands, thyroid glands and tonsils from the definition of rationed meat. It will be observed that liver has not been exempted, notwithstanding the fact that already producers are confronted with a definite shortage of liver for pharmaceutical purposes. During recent years the utilization of liver for the manufacture of materials related to the control of anemia and for vitamin B complex and similar purposes has been greatly extended, so that the amounts now required are far beyond what would have been needed in either 1941 or 1942. Attention must be called, incidentally, to an extraordinary release from the Office of War Information announcing the action taken by the Office of Price Administration. Apparently the Office of War Information is completely without scientific medical advice in the preparation of its releases, since the statement could never have been made by any one with even a modicum of medical information. The release from the Office of War Information reads:

Over and above the actual meat for food which is lost to legal trade, OWI said, strategic by-products are wasted such as materials from which are derived surgical sutures, adrenalin and vital insulin. Sutures are used surgically in the drawing together of the edges of a wound, which is sewn with gut-thread. Adrenalin is a powerful drug obtained from the adrenal glands of animals and is used to check hemorrhage and as a hypodermic injection to check pressure and stimulate the heart. Insulin, among its other applications, is used to retard the formation of sugar in the blood of diabetics.

Who could possibly have informed the Office of War Information that adrenalin is used "as a hypodermic injection to check pressure" or that "insulin

is used to retard the formation of sugar in the blood of diabetics"? What a pity that the opportunity for public education in matters related to medicine and health offered to the Office of War Information by the new regulations should not have been utilized to the utmost advantage by the issuing of information with a reasonable amount of accuracy. For the information of the Office of War Information, adrenalin does not "check pressure" but raises the blood pressure. Insulin does not "retard the formation of sugar in the blood" but restores the ability of the human body to use sugar and fat in the normal manner, enabling the body to burn more sugar in the cells in its tissues.

WAR PRODUCTION BOARD RELAXES RESTRICTIONS ON SCALES

By an action of the War Production Board dated April 29, baby scales will be produced at one fourth the 1941 rate but will be sold to the public only on the prescription of a physician. Previously the production of baby scales for household use had been banned except for clinical type scales made for sale to physicians and hospitals on A-9 ratings. The partial easing on restrictions of production covering household baby scales was necessitated by several factors, most important of which was the complete exhaustion of all supplies because of the growing demand which resulted from the phenomenal increase in the birth rate. Under the new order the sale of baby scales to doctors, hospitals, distributors and dealers is permitted without restriction. Manufacturers may produce only one model, and that model must be the one made in 1942 which used the least amount of steel. The use of copper and brass is completely prohibited, and metal cannot be used for making the tray. Fiber, paper board, plastics, wicker or cane may be used for the tray. It is anticipated that the saving resulting from these restrictions will hold down the consumption of steel for baby scales to not more than one eighth of the amount used in 1941. Physicians will, of course, give utmost cooperation to the War Production Board in the issuing of prescriptions to their patients for the purchase of these scales. Such cooperation will require that a prescription be not issued except under circumstances in which it becomes impossible for the family to utilize a scale available in the neighborhood or which can be borrowed from any available source. Presumably also physicians will recommend the use of scales only when considered necessary in relationship to routine care of an infant requiring constant study of the weight in relationship to suitable growth. At the same time that the War Production Board authorized the manufacture of baby scales, an order was issued restoring production of dietetic scales used by persons whose diet is under a physician's control to the 1941 levels. These scales also may be sold only on prescription by a physician. The prohibitions on the production, repair and maintenance of scales for household use have been relaxed to the extent that parts may be used for rebuilding used commercial scales into baby weighing scales. Again it should be emphasized that the position of the civilian physician in the war effort is one of the most

responsible and important of any type of professional service rendered to the public. Never before have so many responsibilities been placed even on the physician. Already he has shown in the war effort that the ethics and honor of the profession warrant the belief that he will exercise his functions in the high tradition of the past.

THE ROCKEFELLER FOUNDATION IN 1942

The review of the work of the Rockefeller Foundation in 1942 presented by Raymond B. Fosdick¹ records appropriations of over eight million dollars, over half spent in the fields of public health and medical sciences. Of special interest to the medical profession is the work of the foundation in yellow fever. Today, principally as the result of the work of the foundation, few of our soldiers or sailors need to be victims of yellow fever. Our troops in Liberia and other parts of Africa where yellow fever is endemic are now protected by vaccination from the consequences of this savage disease, with its mortality ranging in some localities as high as 70 per cent. During 1942 much attention was given to an outbreak of jaundice which appeared to be associated with certain definite lots of yellow fever vaccine. In preceding years nearly eight million vaccinations had been successfully administered without disturbing consequence except for a few cases of jaundice in Brazil. Research during 1942 indicated that the incidental jaundice which is not contagious and does not constitute a danger to public health is probably due to a virus in the human serum component employed in the vaccine. Oddly enough, cases of jaundice appeared in England and Russia, apparently following the administration of vaccines or serums which were manufactured in those countries for diseases other than yellow fever and which also contained a human serum component. Now yellow fever vaccine is being successfully made without this component. Fosdick's report mentions also the research being developed in the laboratories of the foundation and elsewhere on synthetic drugs designed to replace the now scarce quinine. The foundation has also supported psychiatric studies, medical education, research in the biologic sciences, the training of British medical students in the United States and various important programs in the humanities and the social sciences. The contributions to various abortive movements and executive secretariats concerned with fermenting changes in the nature of medical practice seem somewhat out of harmony with the nature or previous practices of this foundation. Because of the disastrous effects of wartime inflation, the work of the foundation as well as of other American agencies in China has deteriorated rapidly and has reached a critical stage. As Fosdick suggests and as the work of the foundation is designed even a relatively small sum may be used effectively to help build a bridge between what men have valued in the past and what they hope to maintain in the future.

RHEUMATIC FEVER IN CHILDREN

The serious character of rheumatic fever as a cause of heart damage to children, and indeed as a cause of death, has made it desirable to refocus medical attention on this disease. Rheumatic fever now ranks among the leading causes of disability and is generally recognized as an important public health problem in this country. The states of Michigan, Iowa, California and Rhode Island, the District of Columbia, Cincinnati and Chicago make this disease reportable. For other sections of the country accurate statistics are not, therefore, available. Nevertheless there is evidence that the death rates in certain areas are exceedingly high, notably in New York, Pennsylvania, New Jersey and Delaware as well as in Idaho, Montana, Colorado and Utah. With a view to aiding the movement toward better recognition and control of this condition, the Metropolitan Life Insurance Company has issued a pamphlet on rheumatic fever in general which has been approved by the American Heart Association, the American Academy of Pediatrics, the United States Public Health Service and the Children's Bureau of the Department of Labor. In the development of the pamphlet some seventeen authorities cooperated with the medical director of the company and its medical staff. The booklet, which is distributed without cost to practicing physicians, provides a complete consideration of the most recent information on the subject, a bibliography and five appendices with methods of examination, laboratory tests, outlines for classifications of murmurs and outlines of the activities in which patients may indulge. Already several state medical societies have arranged to place it in the hands of all their members.

UNIFORM DEFINITIONS OF MOTOR VEHICLE ACCIDENTS

Comparative figures on motor vehicle accidents occurring in different areas have been difficult to obtain chiefly because of variations in the use and interpretation of definitions by the various official and unofficial agencies involved. In an attempt to meet this problem the Committee on Definitions of the National Conference on Uniform Traffic Accident Statistics under the chairmanship of Dr. Halbert L. Dunn, chief statistician for vital statistics of the Bureau of the Census, has prepared a manual¹ of uniform definitions. This manual defines such terms as "fall from motor vehicle," "injury to nonoccupants," "street wear and tear" and "terminating on a trafficway." The standards set up should be determined by individual agencies and organizations to suit their specific purposes but in order to secure uniformity in the published data the provisions of this manual should be rigidly followed in the classification of motor vehicle accidents for general publication purposes. The desirability of following these recommendations is manifest.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY AND NAVY MEDICAL TRAINING PROGRAM

Official Announcement on Details of Army and Navy Programs for Training Medical Students

ARMY PROGRAM FOR STUDENT TRAINING

In order to assure the Army the annual loss replacements for medical dental and veterinary officers, the Army Specialized Training Division has been directed to train a sufficient number of enlisted men who, on receipt of the appropriate degree in medicine dentistry and veterinary medicine, may be appointed in the Medical, Dental or Veterinary Corps, Army of the United States. Such training will include both a pre-professional and a professional phase and as far as possible will be continuous. To this end basic military training will not be required of enlisted men of the Enlisted Reserve Corps who are bona fide preprofessional and professional students and who, when called to active duty are finally selected for premedical or medical training under the Army Specialized Training Program. Basic military training will be, however, required of all other groups.

Enlisted Men

Enlisted men recommended by Army Specialized Training Program Selection Boards for assignment for such preprofessional or professional training, at any level, must be thoroughly qualified as regards fitness and aptitude for subsequent professional training. Their scholastic ability likewise must be such that attrition in both the premedical and medical phases will be held to a minimum.

Students in Medical Administrative Corps

There are now in approved schools of medicine, dentistry and veterinary medicine approximately 22,000 students who hold commissions in the Medical Administrative Corps, A U S, or in the Officers Reserve Corps and who are on an inactive status for the purpose of completing their professional training with a view to appointment in the Medical, Dental or Veterinary Corps, A U S. The discharge of these students, at their own request, from their commissions and their enlistment in the Enlisted Reserve Corps has been authorized. Students so enlisted will be ordered to active duty at the end of the academic period which terminates between April 15 and June 30, 1943 or, if the academic period continues beyond the latter date, on June 30, 1943. Orders calling such enlisted men to active duty will be issued fifteen days prior to termination of the academic period or June 30, 1943, whichever is applicable. These students will be invited to submit letters of resignation for the purpose of enlistment in the Enlisted Reserve Corps.

Contracts will be requested with all approved schools effective not later than the beginning of the next academic term which ends before June 30, 1943.

ROTC Students

First and second year advanced course ROTC medical students who hold commissions in the Medical Administrative Corps, A U S, or in the Officers Reserve Corps and who resign their commissions and enlist in the Enlisted Reserve Corps will be called to active duty as prescribed. Those not in the Enlisted Reserve Corps may be voluntarily inducted for subsequent transfer to the Enlisted Reserve Corps and call to active duty.

Assignment of Students

Medical, dental and veterinary students in good standing in approved schools of medicine, dentistry and veterinary medicine, not under Army jurisdiction, if inducted under Selective Service subsequent to June 30, 1943, will be assigned with the least practicable delay to the Army Specialized Training unit at the institution in which currently matriculated.

The total number of college students pursuing approved premedical, predental and preveterinary courses is greatly in excess of the capacity of approved schools of medicine, dentistry and veterinary medicine. It is emphasized that these trainees are soldiers assigned for university training rather than "students in uniform." Premedical, predental and preveterinary students in the Enlisted Reserve Corps will be called to active duty and assigned to an appropriate Specialized Training and Reassignment unit for classification and reassignment. Enlisted men recommended by selection boards at specialized training and reassignment units for continuation of their preprofessional training or for professional training will at the proper time be assigned to an appropriate Army Specialized Training Unit. Those not recommended for such training will be assigned to an appropriate replacement training center for the completion of the required period of basic military training or, for those not recommended for any phase of Army Specialized Training to an appropriate unit or installation within the territorial limits of the service command.

Induction Under Selective Service

Premedical and predental students only, not in the Enlisted Reserve Corps, if inducted under Selective Service subsequent to the end of the academic period which terminates prior to June 30, 1943 or, if the academic period continues beyond this date, subsequent to June 30, 1943, reporting at reception centers, will, if they attain a score of 115 or better on the Army General Classification Test, be transferred to a Medical Department Replacement Training Center if practicable or to an appropriate installation within the geographic limits of the service command for basic military training. Such men will be designated as candidates for the Army Specialized Training Program. They will there appear before the Army Specialized Training Program field selection board for selection or rejection for the Army Specialized Training Program. Enlisted men who have completed the required preprofessional schooling and have been recommended for professional training by the Army Specialized Training Program selection board at a Specialized Training Assignment and Reclassification unit, but for whom there are no appropriate immediate vacancies in contracting schools of medicine, dentistry and veterinary medicine, will be assigned to a Medical Department Replacement Training Center and/or to other service command installations, preferably with the Medical Department, pending assignment to a suitable unit within prescribed quotas, for professional training.

The procedures for the selection of enlisted men for assignment for training in medicine, dentistry and veterinary medicine under the Army Specialized Training Program will be no less thorough and exhaustive than those now in common usage for acceptance for admission to the accredited professional schools throughout the country.

NAVY PROGRAM FOR STUDENT TRAINING

Medical students who at present hold commissions as Ensigns H-V (P), USNR have the option of remaining on inactive duty in their present status until completion of their course in medical school at their own expense or they may resign their commission and enlist as Apprentice Seamen U S Naval Reserve, and be placed on active duty with pay, uniforms and a per diem allowance to defray the cost of their subsistence. The tuition will be paid by the Navy, including the cost of books and the cost of renting microscopes or other equipment necessary in the medical courses.

Entering Students

Students who are now in medical school, or those who have been accepted to the next entering classes, who are Ensigns H-V (P) USNR will continue in these schools. On satisfactory completion of the prescribed course of studies, the students will be commissioned in the Naval Reserve as Lieutenants (junior grade) MC-V (G) on an inactive duty status to complete one year of internship in a civilian hospital. Those students who desire to enter the Medical Corps of the regular Navy and successfully pass the examination will be assigned to an internship in a naval hospital on active duty.

If the student fails to maintain satisfactory standards on active duty in the Navy College Training Program, he may be assigned to general duty in enlisted status in the rating for which qualified. The pay of Apprentice Seamen on active duty, without dependents is \$50 per month. Certain allowances are made for the dependents of an Apprentice Seaman on active duty contingent on the allotment by the man concerned of a portion of his pay to his dependents. The amounts of the allowances depend on the number and relationship of the dependents.

Ensigns

Married Ensigns H-V (P) USNR are eligible for enrolment and participation in the Navy College Training Program. The maximum age restrictions prescribed for other Apprentice Seamen in the Navy College Training Program are not applicable to former Ensigns H-V (P).

Former Ensigns H-V (P) who enlist and who are attending medical school on or about July 1, 1943 will be ordered to active duty at the school which they are attending at that time.

Navy medical students in the Navy College Training Program will pursue an accelerated course. While on active duty in school, medical students will wear a Midshipman or Cadet type uniform with suitable distinguishing insignia.

Applications for appointment as Ensigns H-V (P), USNR, from civilian students in medical school, or those students who have been accepted for admission to the next entering class of an approved school, will not be accepted after June 1, 1943. Thereafter qualified students who are in attendance at or who have been accepted by an approved medical school will, on approval by the Bureau of Medicine and Surgery and the Bureau of Naval Personnel be inducted as Apprentice Seamen, Class SV-12 (S), for training in the Navy College Training Program.

Premedical Students

Premedical students assigned to colleges and universities participating in the Navy College Training Program will be made up mostly from premedical students who now hold an enlisted rating in class V-1 or V-7, USNR. A small percentage of premedical students will be taken from the successful applicants who passed the test given on April 2, 1943 in all high schools and colleges in the country. Tests will be given again in November 1943 and in March 1944.

Premedical students formerly in class V-1 and V-7, on active duty in the Navy College Training Program, who are not selected for medical training by the Navy but who are acceptable to an approved medical school may submit request to the Bureau of Naval Personnel for discharge. Each such request will be considered on its own merits. If not acceptable to an approved medical school such men will be considered candidates for other officer candidates training in which qualified.

The course of studies for premedical students entering the first term on July 1, 1943 will run for five terms of sixteen weeks each. It is proposed to screen premedical students after the first year of their studies. The successful students will continue their course until completion, the failures will be allowed to continue the term they are in at the time of failure and then be assigned other training. It is the intention of the Navy Department that Naval trainees, pursuing a premedical course and later assigned to medical schools, be acceptable to the schools to which ordered.

CIVILIAN DEFENSE

CIVILIAN DEFENSE AFFILIATED
MEDICAL UNITS

The following resolution has been passed by the Directing Board of the Procurement and Assignment Service:

As a measure of protection for the civilian population in case of enemy action, the United States Public Health Service in cooperation with the Medical Division, Office of Civilian Defense, has invited selected hospitals and medical schools to organize affiliated units of physicians in accordance with a specific table of organization. The physicians of these units are asked to accept reserve commissions in the U S Public Health Service on an inactive status with the understanding that they will be called to active duty only for the following purposes:

- 1 To provide medical care for civilians who must be moved out of their communities of residence as the result of enemy action.

- 2 To provide temporary medical care in extreme emergency for military personnel in extemporized hospitals in the area.

Affiliated units will be called to active duty only on the recommendation of the respective state chiefs of Emergency Medical Service. In selecting units for activation, the state chiefs will call on those physicians who can best be spared temporarily from their civilian practices. By virtue of this arrangement, civilian medical needs will be safeguarded against haphazard withdrawal of physicians in an emergency.

The Directing Board of the Procurement and Assignment Service fully approves of the formation of affiliated units for the purpose outlined and urges all state chairmen of the Procurement and Assignment Service to facilitate the organization of these units in every way possible. Applicants for U S P H S reserve commissions for service in the affiliated units should not be cleared with the Procurement and Assignment Service because the terms of their commissions fully protect the civilian medical needs of the communities in which the units are being organized. It is understood that the U S Public Health Service will accept applications only from the following groups: (1) physicians 45 years of age or older, (2) women physicians, (3) physicians of any age who are physically disqualified for military duty, (4) physicians already declared by the Procurement and Assignment Service to be essential for civilian needs.

In the case of each physician under 45 who is being considered for such a commission and who is physically fit for military duty, it is understood that the U S Public Health Service will obtain from the local Procurement and Assignment Service chairman concerned assurance that the physician has already been declared essential for civilian needs. The fact that Reserve Officers of the U S Public Health Service are now classified as 4-B by Selective Service does not affect this arrangement since the Public Health Service has agreed that if such physicians holding inactive reserve commissions are subsequently declared by the Procurement and Assignment Service to be available for military duty, they will be permitted to resign their commissions.

APPOINT SUPERVISOR OF RESCUE SERVICE PROGRAM

Simon H. Ash, head of the mineral production security division of the U S Bureau of Mines and a leading mine safety engineer, has been appointed to supervise the Office of Civilian Defense Rescue Service Program and will leave for England to study the British civilian rescue service and its experience under air raid conditions. On his return Mr. Ash will set up a school for the training of civilian defense rescue officers. The director of civilian defense, James M. Landis, said in the announcement that the British have discovered that a highly specialized type of rescue crew is necessary to save the lives of victims trapped by the collapse of buildings during a bomb-

ing attack. Mr. Ash has directed rescue operations involving practically every type of mine, quarry and tunnel disaster and has been safety engineering consultant for many of the largest terminals and underground construction projects. He was born in the state of Washington, began working in coal mines at the age of 14, and later attended Lehigh University and the University of Washington, from which he received a degree in mining engineering. For three years Mr. Ash has represented the Bureau of Mines on the National Resources Planning Board. For the purpose of enabling him to carry out his new duties, Mr. Ash has been commissioned in the U S Public Health Service and assigned to the Office of Civilian Defense.

ARMY

BRIGADIER GENERAL NORMAN T. KIRK NOMINATED FOR SURGEON GENERAL

The nomination of Norman T. Kirk to be Surgeon General of the Army with the rank of major general has been sent to the Senate by the President. General Kirk, who is 55 years old, was until recently commanding general of the Percy L. Jones General Hospital in Battle Creek, Mich. He was formerly chief of the surgical service at the Army Medical Center at the Walter Reed General Hospital, Washington, D. C. He entered the army medical corps in 1913 with the rank of first lieutenant. He is to succeed Major Gen. James C. Magee, whose term expires on June 1.

THE HALLORAN GENERAL HOSPITAL

The Paul Halloran General Hospital is a 3,000 bed army general hospital located on 383 acres of partly wooded land in the middle of Staten Island, New York, and is established as a separate military post, directly under the commanding general of the Second Service Command, Services of Supply, Governors Island, N. Y.

The hospital proper was built by the state of New York and consists of forty-three brick buildings of Georgian architecture in addition to a series of army hospital clinics, such as surgery, x-ray, laboratory, physical therapy, dental and detachment barracks. Construction of the buildings was started by the Department of Mental Hygiene of the State of New York in 1939. A shortage of critical materials prevented final completion, and the buildings had never been occupied. After preliminary surveys by Surg. Gen. James C. Magee, it was decided that the site and buildings offered great possibilities for use as an Army General Hospital. A survey by the Army Corps of Engineers was made in July 1942, and the buildings were finally turned over to the Army on October 14. Extensive alterations have been made to the buildings. The hospital received its first patients on November 5.

The hospital was named in honor of the late Col. Paul Stacy Halloran, a distinguished officer of the Medical Corps of the U S Army.

The staff is in part as follows:

Col. Ralph G. DeVoe, M. C., Commanding Officer
Col. Edward N. Piekard, M. C., Chief of Medical Service
Lieut. Col. Alonzo T. Briney, D. C., Chief of Dental Service
Lieut. Col. Vansel S. Johnson, M. C., Chief of Surgical Service
Major George K. Carpenter, M. C., Chief of Orthopedic Section, Surgical Service
Major Joseph A. Crisler Jr., M. C., Assistant Chief of Surgical Service
Major Kenneth M. Kahn, M. C., Registrar
Major Arnold M. Kallen, M. C., Hospital Inspector
Major Harold P. Lewis, M. C., Assistant Chief of Medical Service
Major Joseph Rothman, M. C., Chief of Officers' Medical Section
Major Charles H. Schutt, M. C., Plans and Training Officer
Major Thomas P. Shearer, M. C., Chief of Genitourinary Section, Surgical Service
Major Arthur B. Soule Jr., M. C., Chief of X-Ray Service
Major George A. Vassos Jr., M. C., Executive Officer, Public Relations Officer

Major Thomas B. Wiper, M. C., Chief of Septic and Thoracic Surgical Section, Assistant Chief of Surgical Service
Capt. Melvin I. Ames, M. C., Assistant Chief of Officers' Section, Medical Service
Capt. Charles V. Amole, M. C., Genitourinary Section, Surgical Service
Capt. George S. Baker, M. C., Chief of Neurosurgical Section, Surgical Service
Capt. Theodore Baker Jr., M. C., Chief of Laboratory Service
Capt. John M. Buchanan, M. C., Chief of Tuberculosis Section, Medical Service, Assistant Plans and Training Officer
Capt. William S. Conway, M. C., Chief of Ear, Nose and Throat Section, Surgical Service
Capt. Edmund J. Croce, M. C., General Surgical Section, Surgical Service
Capt. Arthur G. DeVoe, M. C., Chief of Eye Section, Surgical Service
Capt. Henry L. George Jr., M. C., Chief of Communicable Disease Section, Medical Service
Capt. Hazen L. Hauman, M. C., General Surgical Section, Surgical Service, Chief of Officers Section
Capt. Thomas A. Johnson, M. C., Chief of Gastrointestinal Section, Medical Service
Capt. Sidney Katz, M. C., General Surgical Section, Surgical Service, Assistant Plans and Training Officer
Capt. John W. Kayes, M. C., Chief of Cardiovascular Section, Medical Service
Capt. Carmello P. Locasto, M. C., Chief of Dermatology and Syphilis Section, Medical Service
Capt. William S. McCullagh, M. C., Chief of Neuropsychiatry Section, Medical Service
Capt. Karl F. Meck, M. C., Orthopedic Section, Surgical Service
Capt. George E. Paulsen, M. C., Anesthesia and Operating Section, Surgical Service
Capt. Robert T. Rosenfeld, M. C., Orthopedic Section, Surgical Service
Capt. Thomas D. Thompson, M. C., Orthopedic Section, Surgical Service
Lieut. Raymond L. Abraham, M. C., Chief of Obstetric and Gynecologic Section, Assistant Plans and Training Officer
Lieut. Louis C. Acquarulo, M. C., Orthopedic Section, Surgical Service
Lieut. Isidore R. Cohen, M. C., General Medical Section, Medical Service
Lieut. Michael J. Dardis, M. C., Chief of Outpatient Service
Lieut. Benjamin F. Dennis, M. C., Neuropsychiatric Section, Medical Service
Lieut. Frank T. W. Drews Jr., M. C., Orthopedic Section, Surgical Service
Lieut. Lloyd E. Hawes, M. C., Assistant Chief, X-Ray Service
Lieut. Robert W. Mann, M. C., General Surgical Section, Surgical Service
Lieut. John S. McQuade, D. C., Dental Service
Lieut. Joseph M. Miller, M. C., Septic and Thoracic Section, Surgical Service
Lieut. Moore A. Mills, M. C., Receiving and Disposition Officer, Chief of Tropical Medicine Section, Medical Service
Lieut. Kurt Nussbaum, M. C., Neuropsychiatric Service, Medical Service
Lieut. Nicholas R. Occhino, M. C., General Medical and Tuberculosis Section, Medical Service, Pharmacy Officer
Lieut. William S. Rhode, M. C., Neuropsychiatric Service, Medical Service
Lieut. John R. Sharp, M. C., Upper Respiratory Section, Medical Service
Lieut. Darrel T. Shaw, M. C., Chief of Plastic Surgical Section, Surgical Service
Lieut. Raymond J. Sherer, M. C., Dermatology and Syphilis Section, Medical Service

FEMALE PHYSICIANS

On April 16 the President signed a bill enabling the commissioning of women in the Medical Corps for duty as physicians. No similar authority exists with regard to dentists or veterinarians. The procedure outlined for the processing of male physicians will apply to the processing of female physicians. No female physician will be processed until the District Office has received her availability clearance form from the state Procurement and Assignment physician chairman. It is anticipated that some delay may ensue before the Surgeon General will be in a position to recommend female physicians for appointment, because regulations and forms must be prepared and issued. Whereas district offices are authorized now to process any female physicians whose availability may be declared by the Procurement and Assignment Service, such candidates should be advised that there will probably be a considerable time lag in the consideration of their cases by the Surgeon General. Until further instructions, district offices will use the same forms and procedures in processing female physicians as are in use for male physicians. Female physicians processed and appointed will count against, and are not in addition to, the total figure for physicians in the Surgeon General's 1943 program.

CHANGES IN MEDICAL OFFICERS

Dr A William Reggio, Boston, recently state chief of emergency medical service for Massachusetts, has been appointed regional medical officer for the first civilian defense region (the New England states), succeeding Dr Dudley A Reekie. Dr Reggio was formerly instructor in surgery at Harvard Medical School and assistant visiting surgeon at the Massachusetts General Hospital. Dr Reekie, who was acting chief of the field casualty section, has since been assigned by the Surgeon General, U S Public Health Service, to the U S State Department to head a group of Public Health Service officers who will act as special advisers on health matters to Robert Murphy, chief civil affairs officer for North Africa. To succeed Dr Reekie as acting chief of the field casualty section, Dr H van Zile Hyde, regional medical officer for the second civilian defense region (New York, New Jersey and Delaware), has been transferred to Washington. Dr John J Bourke, deputy state chief of emergency medical service for New York, is now acting regional medical officer for the second region.

Dr David D Rutstein, medical gas officer on the Washington staff, has resigned to become deputy health commissioner of New York City. Before he joined the medical division, Dr Rutstein was chief of the cardiac bureau of the New York State Health Department, Albany.

MISCELLANEOUS

QUINACRINE PLACED UNDER
ALLOCATION

Quinacrine, a synthetic chemical having antimalarial properties similar to those of quinine, which is now almost unobtainable, was placed under allocation on April 2 by the War Production Board through issuance of General Preference Order M-306. Quinacrine is also produced under the trade name of atabrine. A producer seeking authorization to deliver or use quinacrine in any month beginning with May 1943 must file application with the War Production Board on form PD-602 by the 20th of the preceding month. In addition, each producer is required to file by the 5th of each month, beginning with May, with WPB on form PD-602 a list of civilian customers to whom he made deliveries in the preceding month. A producer is defined in the order as a person who produces or imports quinacrine or has it prepared for him or who makes quinacrine tablets or other dosage forms of quinacrine except ampules.

DEVICE FOR FOLDING SURGICAL
DRESSINGS

E I du Pont de Nemours and Company, Inc, Wilmington Del, announces the invention and mass production of a device that folds surgical dressings three to five times faster than by hand. The inventor, Philip W Buttnham, an engineer with the du Pont Company, and more than a score of other experts and officials rushed to completion the device within four weeks to aid the Wilmington Red Cross chapter in meeting huge army and navy quotas for surgical dressings. While the Delaware Red Cross has adopted the device it will not be available on a national scale until officially adopted by the American Red Cross. The device is so simple to operate that Delaware school children are being organized for this work. The turnover among volunteer Red Cross workers is expected to be far less, it is said now that the surgical dressing folding job will be less monotonous and tiring. Harry J Haon, director of the Delaware chapter, said that the local Red Cross chapter fell behind its quota for dressings by several hundred thousand for the first quarter of this year, despite breaking all previous production records. If this condition applies nationally, the new folding device would aid the many chapters more nearly to meet their quotas of surgical dressings. While more workers are urgently needed, Mr Haon is sure that many volunteers will come forward when the new folding devices are available. The plans, specifications and all rights to the appliance are being given to the Red Cross.

PUBLIC HEALTH UNDER HITLER

According to NDZ of February 15, the Reich Committee for Medical Research into Work and Output (Reichsarbeitsgemeinschaft für Arbeits- und Leistungs-Medizin) was set up in Berlin February 21. It will combine, under the leadership of the DAF, all research activity in this field. On this occasion the director of the Office for Health and Protection of the People, Dr Bockhacker, spoke to representatives of the press about the wartime tasks in connection with health measures in the factories.

The employment of doctors in the factory itself has during the last few years become an integral part of factory life. The war makes it necessary to pay more attention to the health of the working people. The call for higher output and especially the appeal to women must not involve injuries to health. It is the task of the works doctors to insure this, and the scope of their preventive activities has recently been further extended by the introduction of medical inspections at the place of work. This does away with the long periods of waiting in surgeries and leads to considerable economies in working hours.

The system of works doctors has revolutionized the work of medical care for the working people and the results of this are visible in the good state of health of the workers. Even in occupations in which there is considerable danger the general state of health is so outstandingly good that absence from work amounts to only 3 per cent on the yearly average. In some instances medical inspection in the factories has even reduced absenteeism below the peacetime frequency. More than 5,000 factory medical stations partly with auxiliary staffs, have so far been set up. Thousands of doctors have become accustomed to factory life, treating the workers practically on the job. It is the task of the works doctor not to treat sick persons but rather to maintain the health of his charges and to protect them from all influences that might prejudice their power of resistance. He is so to speak the industrial pastor of the workers. Diagnosis of the job is added to the diagnosis of working capacity.

Sept-Jours of January 10 stated that among the illnesses due to food shortage carotenemia has appeared. The greatest menace due to restriction is tuberculosis. It is estimated there were 550,000 dangerous cases of tuberculosis in France before the war. They number 1,000,000 today. Those affected are mostly men and women between 50 and 60 whose old lesions decalcify and release bacilli owing to lack of calcium contained in milk and lack of meat and fats. (Carotenemia is a disease which has recently appeared in France and is due to eating too many vegetables of the carrot type—Ed.)

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Departments of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area where the broadcasts are heard by transcription at 10-30 p m Saturdays over Station WMAQ. Unless otherwise indicated, each program is summarized by Dr W W Bauer, Director, Bureau of Health Education.

The titles and guest speakers for the next four programs are as follows:

May 15 'High Air'
May 22 'Flesh Burns'

Speaker: Rear Admiral Ross T McIntire, M C, Surgeon General, United States Navy

May 29 'Sick Call'

June 5 'Doctors for Tomorrow'

Speaker: Brig Gen Fred W Rankin, President of the American Medical Association

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled "Before the Doctor Comes" will be on the air every Thursday afternoon at 2-45 up to and including May 27. Mrs June Merrill will interview Dr W W Bauer, Director Bureau of Health Education, on common home health problems. The titles for the last three programs are:

May 13 'Growing Pains'

May 20 'Nervous Habits'

May 27 'Immunization'

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

California

Bills Introduced—A 328 proposes the enactment of a hospital lien law applicable to the operators of a public or private hospital which furnishes hospital service to an injured person. The term "hospital service" would include medicines, supplies and roentgenologic, laboratory, nursing and other care and service necessary for the treatment of the injured. A 664, to amend the business and professions code, proposes to authorize the board of medical examiners to examine applicants for licenses to practice physical therapy, which is defined as the treatment of patients by the use of massage, therapeutic massage, exercise, therapeutic exercise, or by the use of the physical, chemical and other properties of electricity (except x-rays, radium and electrosurgery), heat, light or water.

Colorado

Bill Enacted—H 236 was approved, April 20. It enacts a service tax for the state of Colorado but exempts therefrom services rendered by chiropractors, osteopaths, physicians, surgeons and other practitioners of licensed professions.

Delaware

Bills Enacted—S 41 was approved, April 13. It amends the medical practice act by exempting therefrom the treatment of human ills by prayer or spiritual means in accordance with the tenets of any well recognized religious denomination. H 97 was approved, April 16. It amends the workmen's compensation act by authorizing an employee to engage a physician or surgeon other than the one furnished by the employer and to receive from the employer the reasonable cost of the services rendered by such physician or surgeon.

Florida

Bills Introduced—S 182 proposes, in effect, to waive physicians' annual registration fees during the period of their service with the armed forces of the United States or of any allied nation. H 276 proposes that all persons desiring to be married must furnish a certificate from a physician licensed to practice and engaged in the practice of medicine in the state of Florida certifying that such physician has made an examination and found the applicant to be free from any venereal disease.

Illinois

Bill Introduced—H 478 proposes the appointment by the department of registration and examination of an advisory board consisting of three qualified chiropractors to examine applicants

desiring to practice chiropractic, which is defined as a method and system of practical and scientific treatment of the human body for remedial and hygienic purposes without the use of medicine or operative surgery. The proposal would further provide that chiropractic treatment is principally as follows: (1) the use of the hands and fingers in contact with the external surfaces of the human body, (2) manual manipulation, massaging, exercising, rubbing, stretching and adjusting contracted muscles, ligaments and shrunken connective tissues for the purpose of releasing pressure on nerves and relieving abnormal nerve tension, (3) programs of rest, diet, exercise, fresh air, sunlight, elimination of waste and systematic practice of personal hygiene, (4) application of heat and electricity, and hot and cold applications, (5) application and use of modern therapeutic appliances, such as the use of infra-red, ultraviolet rays, short wave electric currents and diathermy treatment.

Massachusetts

Bill Introduced—H 894 proposes that recipients of old age assistance shall receive, among other things, false teeth, eye glasses and hospital and medical services which the aged citizen might need.

Michigan

Bills Enacted—H 250 has become Public Act No 227 of the Acts of 1943. It amends the crippled children's act by limiting professional fees for major operations to \$75 and to \$200 for any one physician for any one patient in any one year. H 264 has become Public Act No 229 of the Acts of 1943. It provides that, where persons entitled to hospital service under a contract for such service are unable to obtain admittance to any hospital because of lack of facilities or accommodations, such contract may provide a method by which such persons may be reimbursed in whole or in part for the expense of nursing and other nonmedical care, restricted to the equivalent of hospital care, required from the illness or injury entitling such person to hospital service.

Missouri

Bills Introduced—S 79, to amend the law relating to food and drugs, proposes, among other things, that a drug shall be deemed to be misbranded if it is sold at retail and contains any quantity of aminopyrine, barbituric acid, cinchophen, dinitro-cresol, sulfanilamide drugs, thyroid or their derivatives, unless it is dispensed on a written prescription signed by a licensed physician, dentist or veterinarian and its label bears the name and place of business of the dispenser, the serial number and date of such prescription, and the name of the prescribing

physician, dentist or veterinarian. H 572 proposes that all residents of the state who are or shall become habitual drunkards, habitual users of opium, cocaine, or of some salt or derivative of these drugs, to such an extent as to become what are commonly called "habitual drunkards," "dope fiends" or "addicts" shall be subject to involuntary confinement in the state hospitals for insane persons for such time as might be necessary to accomplish a cure. H 573 proposes to amend the criminal law concerning abortions by eliminating therefrom an existing proviso exempting instances in which an abortion or miscarriage was procured in order to preserve the life of the mother or unborn child when such action was necessary in the opinion of a duly licensed physician. H 621 proposes the establishment of a sanatorium for the treatment of tuberculous Negroes.

Nevada

Bill Enacted—S Concurrent Resolution No 3 was adopted, March 17. It directs the Nevada industrial commission to make a study and survey of the occupational disease codes and legislation of other states and to make a report thereon at the beginning of the next session of the state legislature.

New Hampshire

Bill Enacted—S 55 has become chapter 122 of the Laws of 1943. It provides for the recognition within the state of hospital service corporations organized under the laws of other states when such other states grant like recognition to New Hampshire hospital service corporations.

New Mexico

Bill Enacted—S 141 has become chapter 83 of the Laws of 1943. It requires every physician who makes a diagnosis of or treats or prescribes for a case of venereal disease to report such case immediately to the municipal or district health officer and authorizes state, district and municipal health officers to detain

and examine persons reasonably suspected of being infected with a venereal disease and to require persons so infected to report for treatment to a reputable physician.

Pennsylvania

Bill Enacted—H 235 has become act 45 of the Acts of 1943. It authorizes the state board of medical education and licensure to issue temporary certificates to physicians licensed to practice in other states after such physician has submitted satisfactory proof to the board that he possesses a license issued by the authorized agency of such other state, that this license is still in effect and has not been revoked or suspended, that he is of good moral character, is not addicted to the intemperate use of alcohol or narcotic drugs, has scholastic qualifications equivalent to those required by law of Pennsylvania and is of satisfactory professional standing in the state from which he comes.

South Carolina

Bill Introduced—H 141 proposes that all medical and hospital expenses shall be an exemption under the state income tax law to the same extent and in the same amount as they are allowed under the federal law.

Wisconsin

Bill Introduced—S 313 proposes, among other things, that no person shall practice medicine, surgery or osteopathy, or any other system of treating bodily or mental ailments or injuries of human beings, under any other Christian or given name or any other surname than that under which he was originally licensed or registered to practice in Wisconsin or any other state. The bill would further provide that no person engaged in the practice of any profession for which a license is required by the state shall change his Christian or given name or his surname to any other Christian or given name or any other surname than that under which he was originally licensed in such profession in this or any other state.

WOMAN'S AUXILIARY

Colorado

In February Mrs. Emily G. Bogert, state commander for the Colorado Society for the Control of Cancer demonstrated to the Woman's Auxiliary to the Denver County Medical Society the methods of making dressings and rolling bandages which are used at the cancer clinics of Colorado General and St. Luke's hospitals. The Visiting Nurse Association of Denver also distributes these dressings. Mrs. George W. Miel opened her home to the group and at the February meeting 100 gauze pads, 111 large combination pads and 100 small combination pads were made and 90 bandages were rolled.

Members of the Mesa County auxiliary have constituted a serving unit working at the hospital two afternoons a month and have just purchased an electric sewing machine for use at St. Mary's. They also are serving in the Red Cross gauze room in the Mesa County Center each Thursday morning.

District of Columbia

A Victory Silver Tea to provide Bundles for America and Smokes for Yanks was one of two special activities undertaken recently by the Woman's Auxiliary to the Medical Society of the District of Columbia. Among the guests were presidents of the women's boards of the local hospitals. Past presidents of the auxiliary assisted at the tea table. The committee in charge of donations reported that \$65 was collected during the afternoon.

The auxiliary is planning a series of buffet suppers and entertainments for medical officers stationed in nearby camps and hospitals. The first of this series was held in the medical society's building on January 23. About eighty officers attended from Walter Reed Hospital, the U. S. Naval Hospital at Bethesda Md., Potomac River Naval Command Headquarters Staff of the Army Air Corps Bolling Field and Naval Air Station. Assistant hostesses at the party were daughters of physicians.

Indiana

The directors of the Woman's Auxiliary to the Allen County Medical Society met at the home of Mrs. E. M. Van Buskirk. The treasurer's report showed a paid membership of eighty-four at that time. Dr. Jessie C. Calvin is general chairman of the Civilian Defense Nutrition Program. Mrs. E. N. Mendenhall is chairman of the organization of neighborhood nutrition classes. Mrs. M. E. Glock is Mrs. Mendenhall's assistant in the organization work. Mrs. Ray Chester is the library chairman, assisted by Mrs. J. R. Adams and Mrs. Ernest Carlo. The duties of this committee are to review books, current magazine articles and commercial literature that are placed on the nutrition shelf and reading table in the public library and the packets carried into the rural districts by the library busses. Mrs. A. C. Worley, chairman of a pediatric project, has Mrs. Carl Moats, Mrs. Doster Buckner, Mrs. C. B. Parker, Mrs. Sterling Hoffman and Mrs. A. Jerome Sparks to assist in providing recreational material for children in the three hospitals. Mrs. Noah Zehr is chairman of the auxiliary Red Cross activities in producing surgical dressings, sewing and administrative work. Mrs. Maurice R. Lohman was chairman of the auxiliary committee in the Minute Woman's Bond Sale campaign during Thanksgiving week. Her committee composed of Mrs. S. R. Mercer, Mrs. N. H. Prentiss and Mrs. Noah Zehr accounted for the sale of \$21,000 worth of bonds. Mrs. Edward Schlegel was city co-chairman of the County Minute Woman's Bond Sale. Mrs. Schlegel has just been appointed a member of the executive board of the county bond sale committee.

New Jersey

A luncheon meeting opened the new year for the auxiliary in the Young Women's Christian Association Jersey City. Mrs. Andrew Ruoff presided and welcomed Mrs. Leah Hornberger, president of the state auxiliary. The dense chairman reported the results from the sale of War Bonds and Stamps by the members in two banks during the week of December 7. Stamps sold amounted to \$925.80 and bonds sold to \$7,425.

Medical News

(PHYSICIANS WILL COLLECT A FAVOR BY SIGNING FOR THIS DELIGHTFUL ITEM OF TWO OR MORE OR EVEN CENTRAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITY, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Physicians Needed—Psychiatrists, anesthesiologists and resident physicians in the specialties of dermatology, syphilology and pathology are being sought for positions in the Los Angeles County Hospital. Applicants for the residencies will be rated on their professional training and experience as evidenced by investigation and interview. An oral examination will be given for the position of psychiatrist and anesthesiologist carrying a salary of \$235 a month. Doctors of medicine under 55 years of age who have completed one year's internship in an approved hospital may file an application for any of the positions. Applications should be filed on or before Friday, May 14. Additional information may be obtained from the Los Angeles County Civil Service Commission, Room 102 Hall of Records, Los Angeles.

ILLINOIS

State Medical Meeting—The one hundred and third annual meeting of the Illinois State Medical Society will be held at the Palmer House, Chicago, May 18-20, under the presidency of Dr. Edward H. Weld, Rockford. Among the out of state speakers will be

Dr. Frank A. Meriwether, Columbus, Ohio (subject to be announced)
Dr. Myne G. Peterman, Milwaukee, Convulsions
Dr. Paul A. O'Leary, Rochester, Minn., Wartime Considerations of Syphilis
Major Murray Sanders, M. C., A. U. S., Epidemic Conjunctivitis
Dr. Gordon I. Harkness, Davenport, Iowa, Industrial Ophthalmology and Otolaryngology
Dr. Ralph L. Campbell, Madison, Wis., Importance of the Outlet Contraction of the Pelvis in Obstetrics

Dr. James E. Paulin, Atlanta, Ga., President-Elect of the American Medical Association, will deliver the annual oration in medicine Tuesday evening. No speaker was announced for the oration in surgery to be given Wednesday morning. Tuesday afternoon there will be a symposium on nutrition by Drs. John F. Carey, Joliet, Henry G. Pouchet, Chicago, John R. Vonachen, Peoria, and Charles A. Aldrich, Chicago. A cardiovascular round table will be conducted Wednesday afternoon by Drs. Francis D. Murphy, Milwaukee, Hermon H. Cole, Springfield, and Edgar M. Stevenson, Bloomington. At the Secretaries' Conference Tuesday evening Hon. H. H. Thomas, British Consulate General, Chicago, will give a talk entitled "The Japanese as I Knew Them" and Dr. Charles H. Phifer, Chicago, past president of the society, will discuss "Latest Developments in Procurement and Assignment." Other groups meeting at the same time will be the woman's auxiliary to the state medical society, the Physicians' Association of the Department of Public Welfare of the State of Illinois, the Illinois Chapter of the American College of Chest Physicians, Medical Women's Association and the Medical Alumni Association of the University of Illinois. An industrial health conference will be a feature of the meeting May 18, with the Central States Society of Industrial Medicine and Surgery and the Chicago Society of Industrial Medicine and Surgery meeting in joint session.

KENTUCKY

Personal—Dr. Joseph Lachman, formerly of Chester, Pa., U. S. Public Health Service, was recently appointed in charge of the Pulaski and McCreary county health departments. Dr. William J. Thomasson, Newport, observed his fiftieth anniversary as a practicing physician on April 15.

Extension Course in Medicine—On May 6 the first of a series of extension courses in medicine sponsored by the Kentucky State Medical Association was held in Corbin. The speakers were Drs. John B. Floyd, Louisville, Walter E. Doyle, Louisville, Percy S. Pelouze, Philadelphia, and Milton J. Wilder, Louisville. Others in the series will be held May 13, with Drs. Doyle, Joseph G. Sherrill, Louisville, Henry H. Caffee, Oneida, and Alice D. Chenoweth, Louisville, May 20, Drs. Doyle, Sherrill, John H. Kooser, Hyden, and Paul A. Turner, Louisville, May 27, Drs. Sherrill, Doyle, Chenoweth and Oscar O. Miller, Louisville.

MASSACHUSETTS

State Medical Meeting—The one hundred and sixty-second annual meeting of the Massachusetts Medical Society will be held at the Hotel Statler, Boston, May 24-26, under the presidency of Dr. George Leonard Schadt, Springfield. Among the out of state speakers will be

Major Stevens J. Martin, M. C., A. U. S., Current Problems of the Army Anesthesiologist
Dr. Thomas Parran, surgeon general U. S. Public Health Service, War-time Responsibilities of the Public Health Service
Brig. Gen. James Stevens Simmons, M. C., U. S. Army, Global Malaria
Col. Richard P. Stroum, M. C., A. U. S., Increased Danger from Tropical Disease in the Present War
Dr. William B. Snow, New York, Physical Therapy in Arthritis
Dr. Russell M. Wilder, Washington, D. C., Medical Nutritional Requirements in the Time of War
Dr. Abram I. Barach, New York, Oxygen Therapy, as Related to Gas Poisoning in War and in Civilian Disasters
Col. John J. Moorhead, O. R. C., U. S. Army, Surgical Lessons of the Pearl Harbor Attack
Dr. Harold A. Cole, Cleveland, Local Use of Sulfonamides in Dermatoses
Major Murray Sanders, M. C., A. U. S., Epidemic Keratoconjunctivitis

The annual oration will be delivered Tuesday morning by Dr. Edward P. Bagg, Holyoke. His address will be entitled "Sunlit Puddles." The Shattuck Lecture will be delivered Tuesday evening by Dr. George W. Thorn, Boston, on "Physiological Considerations in the Treatment of Nephritis." There will be a round table discussion Wednesday on recent improvements in obstetric technique with Drs. Raymond S. Titus, Boston, Joseph W. O'Connor, Worcester, and Arthur F. G. Edgelow, Springfield.

MICHIGAN

Typhoid Carriers—The Michigan Department of Health now has under supervision 276 typhoid carriers. In all, 411 carriers have been identified since 1932, when the search for these carriers was begun. Some have since died or left the state. In 1932 9 known carriers were listed, while reported cases of typhoid totaled 513. Only 20 cases of typhoid have been reported so far in 1943.

Tetanus Toxoid for Farmers and Industrial Workers—The state department of health, Lansing, announces that its laboratories are ready to distribute tetanus toxoid as protection against lockjaw for farmers and workers in industry. The toxoid will be distributed through health officers and physicians and will be used instead of the tetanus antitoxin which has been furnished in the past. The toxoid will also be supplied to all Michigan citizens who want it.

University News—Wayne University College of Medicine, Detroit, has received a grant of \$1,800 from the Ciba Pharmaceutical Products Company for the continuation of a study on the metabolism of estrogens by Warren O. Nelson, Ph.D., Detroit, and one of \$2,500 for vasoconstrictor research under the direction of Dr. Frederick F. Yonkman, Detroit. The Nutrition Foundation, New York, renewed a grant of \$3,600 for Arthur H. Smith, Ph.D., Detroit, to further his soybean study, started last year.

Defects Among Students—Out of 508 Wayne University freshmen who were given physical examinations at the beginning of the semester, only 52 showed no physical defects of any sort, 797 specific defects were reported. According to a report of Dr. Irvin W. Sander, Detroit, director of the Wayne University Student Health Service, most of the defects were of a minor nature as indicated by the fact that 88 per cent of the freshmen were graded as class A, with no restrictions placed on their activities, 10 per cent were graded as class B, with specific types of activity forbidden, and 2 per cent were placed in class C, in which no physical activity is permitted.

NEW JERSEY

State Medical Meeting—The one hundred and seventy-seventh annual meeting of the Medical Society of New Jersey will be held at the Hotel Essex House, Newark, May 25-26, under the presidency of Dr. Elias J. Marsh, Paterson. Features of the meeting will be panel discussions on burns and on virus pneumonia.

Tenth Anniversary of Therapeutic Research Institute—Special ceremonies were held, April 26, to commemorate the tenth anniversary of the opening of the Merck Institute for Therapeutic Research, Rahway. Among the principal speakers were William H. Sebrell Jr., surgeon, U. S. Public Health Service, Bethesda, Md., Dr. Francis G. Blake, New Haven, Conn., and Dr. Russell M. Wilder, Washington, D. C. The Merck Institute for Therapeutic Research, a nonprofit corporation under the laws of the state of New Jersey, was founded in 1933 for the purpose of conducting investigations into the

OKLAHOMA

State Medical Meeting—The Oklahoma State Medical Association will hold its annual session at the Skirvin Hotel, Oklahoma City, May 11-12 under the presidency of Dr James D Osborn, Frederick. Among the speakers will be

Dr Udo J Wile, Ann Arbor, Mich., Rapid Treatment Method for Syphilis
Major Lester D Borough M R C U S Army, Some Neuro-psychiatric Problems Arising in New Army Recruits
Capt Leslie B Marshall M C U S Navy, Naval Medicine
Dr Peter I Russo, Oklahoma City, Spontaneous Gastrocolic Intestinal Report on Two Cases
Dr Harry Wilkins, Oklahoma City, Brain Tumors A Review as a Diagnostic Aid
Dr Andre B Carney, Tulsa, Comparative Symptoms in Peptic Ulcers and Cholecystitis in Two Hundred Cases
Col Monte I Belot M R C U S Army, Problems of Induction
Dr Gregory I Stanbro, Oklahoma City, Carcinoma of the Breast

Other speakers on the program will include Dr Frank H Lahey, Boston, Col William Lee Hart, M C, U S Army, and Gov Robert S Kerr, Oklahoma City

TENNESSEE

State Medical Election—Dr Kyle C Copenhaver, Knoxville, was named president-elect of the Tennessee State Medical Association at its recent annual meeting and Dr Oval N Bryan, Nashville, was installed as president. Other officers elected include Drs Burnett W Wright, Nashville, vice president from Middle Tennessee, Julius C Brooks, Chattanooga, president from East Tennessee, and John W Oursler, Humboldt, vice president from West Tennessee. Drs Harrison H Sholders and Charles M Hamilton, both of Nashville, were reelected secretary-editor and treasurer respectively. This session was a meeting of the house of delegates only.

Members of New Basic Science Board—The governor recently appointed the following members to form the basic science board which was created by the basic science law that became effective February 15. Orren W Hyman, Ph D, Memphis, Dr Edward L Turner and Dr Waller S Leathers, Nashville, George M Cameron, Ph D, and Judson H Robertson, Ph D, Knoxville. At an organization meeting of the board, March 14, Dr Leathers was elected president, Dr Turner, vice president and Dr Hyman, secretary-treasurer. The first examinations were held March 24. Of 192 applicants examined 6 failed. The law requires only candidates for license to practice medicine to take the basic science examination. Candidates for license to practice osteopathy must take the examination if they intend to use drugs in their practice. Candidates for license in chiropractic and in naturopathy are not required to take the examination. All of the applicants taking the March examination were prospective medical graduates. The great majority of them were senior medical students.

WEST VIRGINIA

State Meeting of the West Virginia Medical Association will be held at the D Hotel, Charleston, May 16-18, under the presidency of Dr Robert J Wilkinson, Huntington, and the Kan Society acting as host. Among the

speakers will be Dr J. H. Wilkinson, Huntington, and the Kan Society acting as host. Among the

GENERAL

Association on Mental Deficiency—The American Association on Mental Deficiency will hold its sixty-seventh annual meeting at the Hotel Commodore, New York, May 12-15, under the presidency of Horatio M Pollock, Ph D, Albany, N Y, whose address will be entitled "Mental Hygiene and Mental Deficiency." Included among the speakers will be

Dr Herman Yarnel and Joyce V Deutsch, Southbury, Conn, A Clinical and Incephalographic Study of a Group of Patients with Congenital Cerebral Palsy
Dr I Newton Kugelmann, New York, Nutritional Factors in Mental Deficiency
Dr Jost J Michelsen, Boston, Surgical Aspects of Cranial and Intracranial Abnormalities
Dr Frederick C Thorne, Brandon, Vt, Hysterical Manifestations in Mental Defectives
Lieut Samuel R Heath Jr, A B, Fort Bragg, N C, Case Studies of Problem Soldiers

One feature will be a panel discussion on the "Utilization of the Physically and Mentally Handicapped in the War and Postwar Periods."

American Surgical Association—The annual meeting of the American Surgical Association will be held at the Netherland Plaza, Cincinnati, May 13-14, under the presidency of Dr Vernon C David, Chicago. Included among the speakers will be

Capt Waltman Walters and Lieut Hugh R Buti, M C, U S Naval Reserve, Gastric and Duodenal Ulcers in the Naval Personnel
Dr Howard C Naffziger, Dr Horace J McCorkle and Cordula Kohl, San Francisco, Recognition and Management of Acute Trauma to the Pancreas with Particular Reference to the Use of the Serum Amylase Test
Drs Mont R Reid and William A Alheimer, Cincinnati, Peroxide Ointments with Special Reference to Urea Peroxide
Drs Robert Elman and Carl E Lischer, St Louis, An Experimental Study on the Use of Serum Plasma and Amino Acids in the Replacement Therapy of Fatal Shock Due to Repeated Hemorrhage
Dr Walter E Dandy, Baltimore, Improved Diagnosis and Treatment of Ruptured Intervertebral Disks
Dr James C White, Boston, Cerebral Concussions—Alterations in Cerebral Volume, Blood Content and Histologic Changes After Experimental Injury by Acceleration of the Head
Drs Frank H Lahey and Lewis M Hurvath, Boston, The Thyrocardiac—A Review of Six Hundred Cases

Memorial to Dr Robert Tait McKenzie—Contributions are now being accepted for a memorial to Dr Robert Tait McKenzie, Philadelphia, to take the form of a bronze casting of the Column of Youth and a suitable pedestal bearing an appropriate inscription to be placed in a prominent location in the headquarters of the National Education Association of the United States in Washington, D C. The memorial was approved at a meeting of the American Association for Health, Physical Education and Recreation in 1939. In 1941 it was decided that medallions and prints of Dr McKenzie's creations be made available for distribution to contributors of the general fund and that henceforth the cover of the *Journal of the American Association for Health, Physical Education and Recreation* carry a cent of "The Joy of Effort" or of some other one of Dr McKenzie's creations. The medallions and prints are now available and it is hoped that through their distribution honor will be paid to the memory of the late Dr McKenzie, who died in 1938. A graduate of McGill University Faculty of Medicine, Montreal, in 1892, Dr McKenzie was noted as a sculptor, writer and scientist. He was president of the American Association for Health, Physical Education and Recreation from 1912 to 1915, a past president of the Society of Directors of Physical Education in Colleges and a fellow of the American Physical Education Association and of the American Academy of Physical Education.

LATIN AMERICA

New Medical Journals—*Paginas de Pediatria* of Buenos Aires is a monthly journal which made its first appearance with the October issue. Dr Carlos M Pintos is the editor of the journal, which has its headquarters at 1126 L Saenz Peña Street, Buenos Aires. The publication of *Acción Médica* started with the November issue. Headquarters will be those of the *Círculo Médico* of La Paz, Casilla 687, La Paz, Bolivia. The editorial committee is comprised of Drs Florentina Mejía G, Teodoro Von Borries, Carlos Ferrufino B and Hector Aliaga S.

CORRECTION

Capsules Ascorbic Acid—The description of the recently accepted product Capsules Ascorbic Acid of the McNeil Laboratories, Inc, appeared in THE JOURNAL March 27, page 1008. The sizes were given as 20 mg and 100 mg. The 20 mg dosage form should be 50 mg.

Preliminary Negotiations for Providing a Medical Service for All

As stated in previous letters the government proposes to organize for the first time in this country a complete medical service—domiliary and hospital general and special free to all. This momentous step is receiving close consideration from the British Medical Association and other medical organizations. The minister of health has invited representatives of the main medical bodies to meet him and consider his suggestions on the procedure to be adopted for consultation between him and the medical profession. At the meeting he proposed the establishment of a committee representative of the medical profession as a whole to consider with him and his officers the many problems and difficulties involved. It was agreed that the committee would not have power to commit the medical profession either in principle or in detail and that the discussions will take place not on the basis of any preconceived plan but "from the ground." When the government after consultation, is ready to indicate in general terms the measures proposed these will be submitted, before any final decision is reached to the various medical bodies represented for their consideration. In the case of the British Medical Association this will mean that the proposals will be considered by the council and all committees the divisions and the representative body. Divisions will be asked to ascertain the views of nonmembers as well as of members of the association. Only after decision by the representative body will the association be asked to commit itself.

Consultations have been proceeding between the British Medical Association, the Colleges of Physicians, Surgeons and Obstetricians and Gynecologists and the Society of Medical Officers of Health as to the composition of the representative committee to take part though not as plenipotentiaries, in the discussion with the minister and his officers. It has been agreed that a body of thirty-seven members representing in addition to those already mentioned the Medical Women's Federation local medical and panel committees and other bodies. About half the members of the negotiating committee represent various committees of the British Medical Association, and the majority of these are general practitioners.

The British Medical Association recognizes that as far as possible every step should be taken to give doctors on war service an opportunity to express their views on any plan put forward by the government. For this purpose machinery will be put in motion for communicating with them individually when their views cannot be ascertained through the usual channels. Perhaps never before has there been so much need for unity within the profession. The present phase is one of consultation without commitment. The British Medical Association says that it is inevitable that any scheme of reorganization affecting deeply the medical profession should be the subject of discussion difference and controversy. What is now necessary is that the profession should have confidence in those representing it in preliminary discussion, awaiting the time when through its own organization it can examine proposals and express considered views. In an editorial article entitled

"A United Front" the *British Medical Journal* states that the history of medical organization is for the most part one of dissension petty squabbles and narrow sectarian views. It therefore asks for a united front in the difficult months which lie ahead.

Scientific Freedom and Social Medicine

An article in the *British Medical Journal* (February 20, p. 227) on scientific freedom and social medicine by Dr. Geoffrey Bourne has attracted great attention because of its force. He points out that under the Beveridge scheme the present voluntary hospitals (so called because supported and controlled by voluntary subscribers) will probably come under some form of state or local council control. If the planning is left in the hands of the politicians and civil servants of the state it will almost certainly be modeled according to the traditions of the civil service and along the lines of the emergency medical service and the London County Council hospitals. The defects of the civil service in the stifling of initiative and the shunning of responsibility are notorious. We have now two types of medical service—the autocratic as typified in the two just mentioned and the democratic as typified by the voluntary hospitals. In the autocratic full power is in the hands of the chief medical officer. He delegates it to the medical superintendents of the hospitals who wield it over their subordinate officers. In the democratic institution full power over medical matters is entrusted to the democratic medical committees, composed of practicing physicians and surgeons who are experts in their several lines. In the autocratic system the power over medical matters resides in one man whether he is head of the service or the institution. One man is incapable of having a good knowledge of all branches of medical science and no man is without personal predilections, sympathies or antipathies, whether as to men or as to other things. Promotion to the autocratic status goes by seniority and political and administrative acumen. Seniority is likely to be assisted by a complacent attitude toward superiors and conservatism of outlook and impeded by a tendency to criticize and by liveliness or originality of outlook and even by devotion to medical practice. In the autocratically run hospital systems a medical officer may not publish a paper without permission from his superiors. It is at the voluntary hospitals that British medicine has been made. There all the great clinicians—Bright, Addison, Graves, Hutchinsonson to mention only the greatest—have done their work. These hospitals also constitute the medical schools. The government is so impressed with their work that in this medical revolution (for it is no less) which it contemplates it has announced that it wants to preserve the voluntary hospital. How this can be done under the Beveridge scheme without the evils of bureaucratic control exposed by Dr. Bourne, is a problem for the English genius for compromise.

Marriages

FRANK EARL POOLE, Clay W. Va., to Miss Edith Mary Weintz of Austinville Va. at Durham, N. C., March 24.

JAMES M. KIRTLLEY to Miss Leola Black, both of Crawfordsville, Ind., at Camp Gordon Ga. February 14.

JOHN SARGENT MORRIS JR. Lynchburg Va., to Miss Matilda Elizabeth Cobey of Albany Ga. April 28.

JOHN BORDEN GRAHAM Goldsboro N. C., to Miss Ruby McKay Barrett in Laurinburg in March.

FORREST RILEY LaFOLLETTE New Salisbury Ind. to Miss Jean Tillotson of Franklin January 30.

STEPHEN R. BARTLETT JR. Hingham Mass. to Miss Marion Whitener at Durham N. C. March 24.

RIPON WILSON La Roche Charleston S. C. to Miss Florence Alexander Savage of Camden April 2.

RALPH E. CROSS, Johnson City Tenn., to Miss Sallie Foley of Memphis in Denver February 18.

JOSEPH JACKSON STOKES to Miss Ardis Bowen Stilwell, both of Charleston, S. C., March 25.

JAMES ARTHUR STUMBO, Martin, Ky., to Miss Mary Frances Alston at Frenchburg, March 23.

Deaths

Harry Gideon Wells * internationally renowned as a pathologist, professor emeritus of pathology at the University of Chicago died, April 26, 1913, aged 67, of hypertension and congestive cardiac failure secondary to heart block.

Dr. Wells was born in New Haven, Conn., July 21, 1875. After graduation from Sheffield Scientific School of Yale University in 1895 he became associated with Rush Medical College as a student and worked as assistant in the laboratories of Drs. Ludwig Hektoen and George H. Weaver. The school was at that time associated with Yale Forest University from which he received his master's degree in 1897. He received the degree of doctor of medicine from Rush Medical College in 1898. After an internship in the Cook County Hospital he continued his studies at the University of Chicago from which he received the Ph.D. degree in 1903. He studied in Berlin during 1904 and 1905. Early in his career he combined teaching with research, serving continuously on the faculty of the University of Chicago with the title of associate in pathology in 1901, instructor 1903, assistant professor, 1904, associate professor 1909, professor 1913 and emeritus professor since 1940. He served also as dean of the University of Chicago School of Medicine from 1904 to 1914.

In 1911 Dr. Wells was made director of medical research of the Otto S. A. Sprague Memorial Institute. During World War I he was a member of the American Red Cross Commission to Rumania (1917-1919) with the rank of lieutenant colonel. For his work in Rumania he received the Star of Rumania from the king.

In his professional career Dr. Wells was associated with most of the important scientific organizations in his field. He had been at various times a member of the Association of American Physicians, the Society for Cancer Research, the Chicago Pathological Society, the American Association of Pathologists and Bacteriologists, the American Association for the Advancement of Science, the Society for Biologic Chemistry, and the National Academy of Sciences. He was twice honored with the presidency of the American Association of Cancer Research and once with that of the American Association of Pathologists and Bacteriologists. His ability as a lecturer and teacher in the field of pathology was widely recognized. He had been called on at various times to give the Christian Fenger Lecture of the Institute of Medicine of Chicago, the Colver Lectureship at the College of Medical Evangelists (Los Angeles) and the Mutter Lecture of the Philadelphia College of Physicians, as well as innumerable lectures before medical societies.

Probably the most noteworthy of the contributions of H. Gideon Wells was his work in the field of chemical pathology. His book on that subject was recognized as unique in its field. Early in his career he had cooperated with Osborne of Yale University in the development of means for identification of plant proteins by methods of immunology. Other volumes in his specialty included "The Chemistry of Tuberculosis" and "The Chemical Aspects of Immunity."

His distinguished pupils and associates were numerous, including Maud Slye, Sc.D., widely known for her work on cancer, and Dr. Esmond R. Long, leader in the field of tuberculosis.

In the American Medical Association Dr. H. Gideon Wells was secretary of the Section on Pathology and Physiology 1908-1909 and chairman of that section 1909-1910.

His students will remember him particularly for the color of his lectures, for his incisive wit, sometimes tinged with burning sarcasm, and especially for the manner in which he made of pathology an extremely vital subject.

Leopold Lichtwitz * New York, Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, Germany, 1900, clinical professor of medicine at the Columbia University College of Physicians and Surgeons, consulting physician and for many years chief of the medical division of the Montefiore Hospital, past president of the German Society of Internal Medicine, was an officer of the German Society for Gastro-Enterology and Metabolic Diseases and the Society for Internal Medicine of Berlin, served with the German army during World War I, formerly chief of the Rudolf Virchow Hospital in Berlin and the City Hospital in Hamburg, author of "Functional Pathology" and "Nephritis", aged 66, died, March 18, at his home in New Rochelle of coronary thrombosis.

Montgomery Leonidas Hinds, Arab, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1891, member of the Medical Association of the State of Alabama, formerly mayor of Arab, medical examiner for the Selective Service Board of Marshall County during World War I,

director of the Bank of Arab, served as second vice president of the First National Bank of Guntersville, aged 77, died, February 18, in the Highland Avenue Branch of the Baptist Hospital, Birmingham, of uremia, pyelonephritis, bronchopneumonia and arteriosclerotic heart disease.

James Kennedy Ashburn * Batavia, Ohio, Medical College of Ohio, Cincinnati, 1900, chairman of the Clermont County Selective Service Board number 2, aged 65, died, February 9, of coronary thrombosis and cerebral embolism.

Frank Levi Baum, Boyertown, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1911, served during World War I, aged 68, died, February 14, in the Homeopathic Hospital, Reading, of hepatitis and cholecystitis.

Shirley Francis Boyce, Hugoton, Kan., Kansas City (Mo.) College of Medicine and Surgery, 1916, member of the Kansas Medical Society, aged 47, died, February 17, in Wichita of acute hepatitis.

John Ira Boyer, Long Beach, Calif., College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles, 1912, member of the California Medical Association, served in the medical corps of the U. S. Army during World War I, aged 56, on the staff of the Seaside Hospital, where he died, February 21, of carcinoma of the liver.

William Elyet Byers, Baltimore, Baltimore Medical College, 1904, formerly demonstrator of anatomy at his alma mater, aged 69, died, February 28, in the Johns Hopkins Hospital of bronchopneumonia and advanced carcinoma of the prostate.

George Pierce Florence, Greenville, Ga., Atlanta School of Medicine, 1911, aged 53, died, February 28, of injuries received in an automobile accident.

Samuel Fuxon * Brooklyn, Tufts College Medical School, Boston, 1923, aged 49, died, February 18, of coronary occlusion.

Robert G. Gamble, Haverford, Pa., University of Maryland School of Medicine, Baltimore, 1884, member of the Medical Society of the State of Pennsylvania, president emeritus on the staff, for many years director of medical services, member of the board of directors and on the consulting staff of the Bryn Mawr (Pa.) Hospital, aged 80, died, March 12, of coronary occlusion and arteriosclerosis.

Wade Gaston, Lost Creek, W. Va., Eclectic Medical Institute, Cincinnati, 1896, aged 74, died in February of coronary thrombosis.

Edwin Robert Girvin, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1875, aged 89, died in February.

Hugh William Graham, Mount Morris, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, member of the Michigan State Medical Society, past president of the Genesee County Medical Society, at one time president of the village of Mount Morris, served as mayor and as president of the board of education for many terms, aged 74, on the staff of the Hurley Hospital, Flint, where he died recently of chronic uremia.

Richard Hardy Gray, San Antonio, Texas, State University of Iowa College of Homeopathic Medicine, Iowa City, 1895, formerly an acting assistant surgeon in the U. S. Public Health Service, aged 80, died, March 9, in the Medical Arts Hospital of prostatic obstruction.

Frank C. Gregg, Austin, Texas, University of Texas School of Medicine, Galveston, 1900, member of the State Medical Association of Texas, served as a lieutenant commander in the medical corps of the U. S. Navy during World War I, chief of the staff of the Brackemidge Hospital, aged 66, died recently in a local hospital of coronary thrombosis.

Henry Hartwell Howell, San Gabriel, Calif., University of California Medical Department, San Francisco, 1879, at one time coroner of Inyo County, aged 96, died, February 21, in Alhambra of bronchopneumonia.

Thomas Jefferson Kelley, Marathon, Iowa, Rush Medical College, Chicago, 1901, aged 74, died, February 6, of cerebral hemorrhage.

William Tilden Kirk, Springfield, W. Va., Maryland Medical College, Baltimore, 1901, aged 67, died, February 13.

Henry Lombert Knight, San Pedro, Calif., Rush Medical College, Chicago, 1884, for many years connected with the Eitel Hospital, Minneapolis, aged 81, died, February 2, of carcinoma of the hip.

Juanita Isabella Lea, Tryon, N. C., Michigan College of Medicine and Surgery, Detroit, 1906, aged 70, died, February 28, of pneumonia.

David S Lillibridge, Mount Vernon Ohio Western Reserve University Medical Department Cleveland 1891 aged 74 died February 28 of cerebral hemorrhage

Oscar M Longenecker Kansas City Kan Kansas City (Mo) Medical College 1899 member of the Kansas Medical Society at one time instructor in materia medica at his alma mater for two years served as superintendent of schools for Miami County and for many years as a member of the local school board of Roadside on the staff of the Vineyard Park Hospital Kansas City Mo aged 76 died February 26 of coronary occlusion

Charles Davis Luckett, English Ind Jefferson Medical College of Philadelphia 1889 aged 81, died March 13 of arterial sclerosis of the coronary artery

George Thomas McMahon Waterloo Iowa Drake University Medical Department Des Moines 1895 member of the Iowa State Medical Society aged 82 died February 22 in Des Moines of cerebral hemorrhage

Dennis Miller, Dallas Texas, College of Physicians and Surgeons Baltimore, 1890 aged 76 died February 20 of cerebral hemorrhage and arteriosclerosis

Charles Lynn Morris, Los Angeles Hahnemann Medical College of the Pacific San Francisco 1913 aged 55 died, February 2

John Henry Morrison, Kirkland Wash Northwestern University Medical School Chicago 1898 aged 69 died in February at the U S Marine Hospital Seattle

William Howard Morrow, Pellwood Pa Jefferson Medical College of Philadelphia 1886 member of the Medical Society of the State of Pennsylvania for many years served on the school board in 1936 at a meeting of the Sixth Commencement District of the Medical Society of the State of Pennsylvania received a certificate for fifty years of medical practice aged 85 died February 4 in a hospital at Altoona of general arteriosclerosis and a fracture of the right hip due to a fall

Henry L Mosher, Lyndhurst N J University and Bellevue Hospital Medical College New York 1925 member of the Medical Society of New Jersey member of the board of health of Lyndhurst served on the staffs of the Hackensack (N J) Hospital and the West Hudson Hospital Kearney, aged 43, died February 22

Donald A Murray @ Seattle, University of Toronto Faculty of Medicine Toronto Ont Canada 1906 member of the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons served as vice president of the Pacific Northwest Orthopaedic Society served during World War I aged 63 on the visiting staffs of the King County Hospital Unit number 1 (Harborview) and the Swedish Hospital where he died February 3, of hypertension and arterio sclerosis with congestive failure

Jens L Ohnstad, McIntosh Minn, Minneapolis College of Physicians and Surgeons, 1903 member of the Minnesota State Medical Association, owner of the City Hospital aged 74, died, February 23 of cerebral hemorrhage

Marshall John Payne @ Staunton Va Jefferson Medical College of Philadelphia 1893, formerly vice president of the Medical Society of Virginia past president of the Augusta County Medical Society fellow of the American College of Surgeons, past president of the Association of Surgeons of the Chesapeake and Ohio and Norfolk and Western Railways, past president of the Rotary Club of Staunton, aged 71, died, February 11 of coronary occlusion

Wesley Hamilton Peck, Highland Park, Ill College of Physicians and Surgeons, New York 1888 member of the Illinois State Medical Society, past president of the Chicago Ophthalmological Society, served on the staffs of the Oak Park (Ill) Hospital Columbus John B Murphy and Mercy hospitals, Chicago and St Francis Hospital Evanston otolaryngologist to the Atchison Topeka and Santa Fe Railway Company aged 79, died, February 26 of myocarditis and hypertension

Colvin C Perdue, Mobile Ala, Tulane University of Louisiana School of Medicine New Orleans 1919, member of the Medical Association of the State of Alabama fellow of the American College of Surgeons on the staffs of the City Hospital, Mobile Infirmary and the Providence Hospital aged 51 died February 4, of chronic myocarditis and cirrhosis of the liver

Sherman Rogers, Tulare Calif College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles 1917 member of the California

Medical Association served during World War I visiting physician to the Tulare and East Tulare hospitals aged 51 died February 19 of heart disease and cirrhosis of the liver

George Francis Rozelle Jr @ Dallas Texas Baylor University College of Medicine Dallas, 1939, aged 33, died recently of pulmonary tuberculosis

Robert Randolph Sisson @ Kitzmiller, Md Medical College of Virginia Richmond 1920 aged 43 died February 21 of acute dilatation of the heart and chronic myocarditis

James Brown Smith, Memphis Tenn University of Tennessee Medical Department Nashville 1893, aged 71, died, February 6

Alonzo De Moines Snyder, Huntington Park, Calif, Kentucky School of Medicine Louisville 1897, member of the California Medical Association aged 71 died February 16, in the Culmore Hospital Los Angeles of carcinoma

Rosecoe Conkling Tarbell, Groton N Y, Syracuse University College of Medicine 1901 member of the Medical Society of the State of New York served as health officer, aged 67 died March 8 of heart disease

Joseph Taliaferro Taylor, Adams Run S C Medical College of the State of South Carolina Charleston 1899, member of the South Carolina Medical Association past president and formerly member of the state board of medical examiners in 1934 was appointed a member of the Sanitary and Drainage Commission of Charleston County, aged 72, died February 20 of heart disease

George Allingham Trueman, Munising Mich, Rush Medical College Chicago 1894 first mayor of Munising 1915-1916 formerly chairman of the Alger county board of supervisors county coroner and president of the Munising township board of education served on the staff of the Munising Hospital aged 72 died suddenly February 22 of heart disease

Charles Edward Tucker, Metropolis Ill St Louis College of Physicians and Surgeons 1892 served as local surgeon for the Chicago and Eastern Illinois Railroad Company, captain in the medical reserve corps of the U S Army not on active duty served during World War I for many years examining physician for the Veterans Bureau aged 74 died February 20, of heart disease

Lynn Seeley Van Gorder, Lynden, Wash University of Oregon Medical School, Portland, 1930 member of the Washington State Medical Association member of the staffs of St Josephs Hospital and St Luke's Hospital Bellingham aged 38, died February 7, of carcinoma of the stomach following ulcers

Vincent Charles Vielhaber @ St Louis, St Louis University School of Medicine 1938 diplomate of the National Board of Medical Examiners aged 29 died, February 25, in St Marys Hospital of glomerulonephritis and hypertensive vascular disease

Arthur Edward Walters @ Springfield, Ill, St Louis University School of Medicine 1905 at one time vice president of the Illinois State Medical Society and president of the Sangamon County Medical Society, served for two terms as president of the Springfield park board, aged 60 died, March 1 of coronary thrombosis

Joshua Thomason Ward, Laredo, Texas University of Texas School of Medicine Galveston, 1898 member of the State Medical Association of Texas, aged 69 died, February 25

Archibald A White, New York, Fordham University School of Medicine, New York, 1920 aged 48, died, February 26

James Richard Williams, Richmond Va Medical College of Virginia Richmond, 1898 member of the Medical Society of Virginia, at one time demonstrator of operative surgery at his alma mater aged 67, died February 18, of hypertensive cardiovascular disease

D L Wood, Killeen Texas College of Physicians and Surgeons Dallas 1905 member of the State Medical Association of Texas aged 71 died February 23, in the Kings Daughters Hospital, Temple of myocarditis and diabetes mellitus

Michael George Yeager @ Mercer Pa, Western Pennsylvania Medical College Pittsburgh 1897, for many years house physician on the staff of the Mercer County Home and Hospital on the staff of the Mercer Cottage Hospital served during World War I physician for the Bessemer and Lake Erie Railroad Company, aged 69, died, February 17, of carcinoma of the lung

Correspondence

HOUSSAY RESENTS CENSORSHIP OF MEDICAL PERIODICALS ADDRESSED TO ARGENTINA

To the Editor—The censorship of the United States has delayed the arrival of some issues of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* in the June 20, 1942 issue of which page 615 the censor has cut out a paper. I have had to write several letters about the censorship problem, and I would appreciate your printing this one.

Since the beginning of the war I have been a firm supporter of the Allied countries, especially France, England and the United States. I have expressed my sympathy in public whenever the occasion arose. During the Spanish civil war I presided over the committee of aid to the Spanish intellectuals. Two years ago I attended for the first time in my life, together with the ex-president of the Argentine Republic, Dr. M. I. de Alvear, the leader of the Socialist party, Dr. N. Repetto, and the ex-minister of foreign affairs, Dr. J. M. Cantilo, a public political meeting the "Cibildo Abierto" of "Accion Argentina" over which we presided and in which we spoke in favor of the Allied cause.

When the United States and Brazil entered the war I expressed openly my warm feelings in sympathy with these countries and I am a supporter of the most thorough cooperation of our country in the war.

I point out all these circumstances in order that you may understand the painful impression produced on me by the methods employed by the Board of Censors of the United States concerning the medical and biologic journals which has decided to forbid the mailing to this country of the November 1942 issue of the *Proceedings of the Society for Experimental Biology and Medicine* because it contains some articles which in the opinion of the Board of Censors may be of use to the enemy. Such procedure, as I understand, contradicts the most elemental principles of freedom.

It is practically impossible to forbid the knowledge of medical methods once they have been published in scientific journals. If some procedure is to be kept secret, and I think it is inhuman to keep secrets in medicine, it must not be published anywhere. The inefficiency of the actual measure is evident, since the journals containing the "secret articles" can be brought from other South American countries by our ships or by other foreign ships, or we can go to read them or ask for photostatic copies of them at any moment (Santiago de Chile is only six hours from Buenos Aires and Montevideo one hour).

Besides, we may know what is being published in the United States by the English medical and biologic journals, to which no censorship is applied. Also we may know what is published in the American journals by the abstracts published in the Spanish journals. Censorship to medical and biologic journals has not been applied even by Germany, as we received the scientific journals from that country until the war with Russia began. Since then we have received the abstracts of German papers which are published in the Spanish medical journals. So that with the present methods of censorship the United States, a friendly country, is the only country in the world that restricts the diffusion of scientific knowledge in Latin America.

Of course, I can by no means agree that the journals objected to should be sent to me with any articles or paragraphs cut out or crossed out as the Board of Censors has proposed. Such procedures resemble those used by the Nazis when they burned books. I prefer the numbers to be held there for the duration of the war better than to receive them with such mutilations. I would never accept such procedure.

To forbid that a method of medical treatment should be known by other men, friends or enemies, is contrary to Christian morality, to medical ethics and to the high principles of freedom and civilization. Not even the Nazis have committed such a fault.

It would be a stroke of puerility and foolish pride to believe that the war can be won by preventing some medical papers from being known by the enemies.

I hope for the sake of the well earned prestige of the United States, and in view of the high moral principles for which that country struggles, that these methods will soon be changed.

With my sincerest wishes for the victory of the Allies, I am,

Respectfully yours,

B. A. HOUSSAY, Buenos Aires

EXTERNAL USE OF COD LIVER OIL

To the Editor—In the report of the Council on Pharmacy and Chemistry on the status of the external use of cod liver oil, *THE JOURNAL*, March 6, I noted two references to my publications on this subject. As these references give a somewhat misleading impression of the scientific findings, I think they should be clarified.

In the paper published in the October 1941 issue of *Annals of Surgery* Dr. Emanuel Papper and I reported that

"In the vitamin A deficient groups, A and G, receiving no cod liver oil locally, the symptoms of vitamin deficiency persisted after wounding. These symptoms included loss of weight, fur changes, anorexia, humpback, crusting of the nose and eyes, and xerophthalmia. The average loss of weight in these two groups was 32 Gm during the period of observation. In group C, where the wounds were treated with cod liver oil, there was an average gain of 16 Gm during the experimental period. Although the symptoms of vitamin A deficiency persisted in some of the animals, they were much less severe and less frequent. This was not due to licking the oil off the wounds, as the metal caps placed on the wounds prevented the animal from reaching the wound with his paws or tongue."

The gain in weight plus the fact that the symptoms of vitamin A deficiency were improved and less frequent than in the group that received no cod liver oil locally seems to indicate that the vitamin A derived from the cod liver oil applied locally cleared up the symptoms of vitamin A deficiency. This seems to be a definite indication that vitamin A and/or D may be absorbed by the local application of cod liver oil.

The following statement appears in the report of the Council

"Brandaleone and Papper studied microscopically the scars occurring in their animals but report no differences which may have occurred as a result of varying treatments."

Nowhere in our article is any mention made of microscopic study of scars. However, there is a paragraph which reads as follows:

"In the wounds treated with cod liver oil, the edges were even in contrast to the irregular edges in the untreated wounds, profuse granulation tissue was evident, and epithelization occurred earlier than in the untreated group, and was more abundant. The wounds finally closed leaving a small, white scar."

This was not referring to any microscopic study. However, a microscopic study was made and was reported as part of a thesis for the degree of medical science at New York University in 1938. The results may be thus summarized:

Microscopic sections of the wounds of normal and vitamin A deficient rats were studied. These rats were subdivided into groups that had cod liver oil applied to the wounds and those that had nothing applied to the wounds. The vitamin A deficient group with nothing applied to the wounds showed pro-

caused retardation in healing. The groups that received cod liver oil on their wounds showed by aid material in the interstitial tissue. The normal group irrespective of the use of cod liver oil showed much more exuberant granulation tissue and earlier evidence of healing than the vitamin A deficient group of rats. However, in the vitamin A deficient group those rats that received cod liver oil locally developed evidence of granulation tissue earlier than the group that received nothing locally. In addition in the group of vitamin A deficient rats with cod liver oil applied locally the wounds showed evidence of more rapid healing and none remained unhealed as long as the group treated received no cod liver oil locally.

The fact that lipid material could be seen in the interstitial tissues is another point indicating the absorption of cod liver oil when applied locally.

HAROLD BRANDARTO, M.D., New York

MEAT PRODUCTS NOT A CAUSE OF TRANSFUSION REACTIONS

To the Editor—My attention has been called to a quotation from the magazine *Good Health* which represents a gross misinterpretation of findings secured in a study on experimental blood transfusion in dogs. I have noted and reported that blood secured from a donor recently fed a mixed carbohydrate protein meal, i. e. one to two hours prior to transfusion, will cause a definite reaction in a fasted recipient despite the fact that the bloods were mutually comparable, that the incidence of reactions was less frequent when the donor was fed protein alone, still less so when fed carbohydrate or when fasted and that reactions never occurred when a fat fed donor was used. Furthermore, a transfusion reaction was never observed to occur when both donor and recipient animals were fed prior to transfusion. I employed as a protein meal the whites of four eggs, as a carbohydrate meal 100 Gm of glucose, and the mixed meal was a combination of the two.

I have felt that this work might provide an explanation of clinically encountered transfusion reactions of obscure origin and I indicated that overeating on the part of a donor shortly before he gives blood might lead to unhappy consequences for the recipient. Nowhere in these studies have I indicated that meat or meat products possess any toxic properties. Therefore the statement as printed in *Good Health* represents a complete distortion and is totally without foundation.

Northwestern University, Chicago

MARMOLA

To the Editor—In the April 17 issue of THE JOURNAL, page 1287 there is a misstatement of fact. You have listed Dr. Benjamin H. Schlomovitz as professor of pharmacology and toxicology, Marquette University Medical School, among those who testified in behalf of Marmola. Dr. Schlomovitz has never been specifically professor of pharmacology and toxicology at the Marquette University School of Medicine. From 1920 to 1923 Dr. Benjamin Schlomovitz was professor of physiology and pharmacology, but for the last twenty years he has not been associated with the Marquette University School of Medicine. This information has been given to Dr. A. J. Carlson, professor of physiology at the University of Chicago.

Examinations of Boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL at May 1 page 57.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners. Parts I and II August 24. Part III June and July at various times at various centers having 5 or more eligible applicants. See Dr. J. S. Rodman 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Dermatology and Syphilology. Written Philadelphia Sept. 2. Oral Philadelphia Nov. 5. Final date for filing application is August 10. See Dr. C. Guy Lane 416 Marlboro St., Boston.

American Board of Internal Medicine. Oral Philadelphia May 29 and Chicago June 21. Written Oct. 15. Final date for filing application is Sept. 1. Asst. Sec. Dr. William A. Werrell 1301 University Ave., Baltimore, Md.

American Board of Ophthalmology. Parts I and II. New York City June 15. October 5. See Dr. John Green 6530 Waterman Ave., St. Louis.

American Board of Pediatrics. Written Locally Oct. 8. Oral New York Nov. 20-21. Final date for filing application is Aug. 1. Starting July 1, 1941 Group I will be abolished. See Dr. C. A. Aldrich 707 Tullerton Ave., Chicago.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts. Strain Accelerating Preexisting Pathologic Condition.—The workman, a man 64 years of age, 5½ feet tall and weighing 200 pounds apparently had diabetes and arteriosclerosis. In the course of his employment in assembling a cabinet it was necessary for him to enter the cabinet and work in a cramped position to place screws in place on the inside. The temperature in the room in which he was working was 75 degrees but it was much warmer inside the cabinet, over which there were steam pipes. He was perspiring freely. His knees buckled and he fell against another employee working with him. A few hours later he died from a cerebral hemorrhage. The industrial commission of Ohio refused an award of compensation, and suit was brought for compensation in the court of common pleas of Hamilton County, which affirmed the finding of the commission and an appeal was perfected to the court of appeals of Ohio, Hamilton County.

That an award of compensation, said the court, is proper if the deceased met his death because of an injury received during and because of the employment causing acceleration of a pre-existing disease cannot be doubted. Arteriosclerosis is what is commonly called hardening of the arteries which, owing to excess of lime deposits, lose their elasticity and thus retard the flow of blood through them. They become brittle and if by reason of strain or exertion the pressure of blood is increased may crack or break. The arteries in the brain are in many cases very small and this brittleness presents a condition of extreme danger to the individual, since a break in one of such arteries is almost certain to cause death on the flooding of the brain area. It is the undisputed evidence of the physicians who attended the deceased workman that while he was working and due to the strain and increased blood pressure and the condition of his arteries, he died because one of the arteries in the brain cracked or split under such pressure flooding his brain and causing his death a few hours after the injury. If the bones of the workman had become porous or unduly brittle because of disease and while trying to drive home a screw his shoulder blade had broken, it can hardly be supposed that compensation should be denied. What difference is there in actual effect in the two situations—a brittle blood vessel, a brittle bone? That the strain that was present in this case was within the meaning of the term "injury" as used in the Ohio workmen's compensation act the court felt clear, since there the term

is defined to "include any injury received in the course of, and arising out of, the injured employee's employment" (117 Ohio Laws, p. 109)

The appellate court accordingly reversed the judgment against the claimant and remanded the case for a new trial—*Saunders v. Industrial Commission* 11 N. E. (2d) 282 (Ohio, 1942)

Dental Practice Acts Power of Licensing Board to Define by Regulation Standards of Professional Conduct—A clothing store in New York operated a "dental credit service" for its customers for dental work to be supplied by cooperating dentists. The "service" would discount by approximately 30 per cent the fee the dentist would fix paying the balance in cash to the dentist and presumably eventually collecting in full from the store customer. Cherry, a dentist licensed to practice in New York, cooperated in this plan and in two years obtained about 25 patients by such means. Proceedings were instituted to revoke or suspend his license to practice dentistry on the grounds that he was guilty of "unprofessional conduct" because by reason of his connection with the credit service he made use of and employed the dental credit agency as advertising solicitors and free publicity press agents to obtain patients. The dental board found him guilty and recommended that he be merely reprimanded because he ceased his connection with the service as soon as he was notified that the service was deemed objectionable by the board. The board of regents of New York, however, rejected the recommendation of reprimand and instead suspended for six months Cherry's license to practice. Cherry instituted court proceedings to set aside the order of the board of regents. The matter eventually reached the Court of Appeals of New York.

The New York dental practice act, said the Court of Appeals, authorizes, as far as is here material, the revocation or suspension of a license to practice dentistry or the reprimanding of a licensee who (1) has advertised for patronage by means of hand bills, posters, circulars, stereopticon slides, motion pictures, radio or newspapers or (2) has been otherwise or in any other way guilty of unprofessional conduct. The acts which Cherry is charged with committing, unless they constitute unprofessional conduct, are not embraced in the grounds for disciplinary action stated in the dental practice act, and the order of the board of regents suspending Cherry's license for six months must be annulled unless it appears that Cherry has been guilty of such conduct. Cherry argued that the term "unprofessional conduct" as specified in the act as a cause for the revocation or suspension of a license is so vague that the legislature has in effect delegated to the board of regents unfettered discretion to determine what shall be sufficient cause for disqualification of a dentist. The legislature, of course, answered the court, could neither grant to an administrative board or quasi-judicial tribunal the power to impose a penalty on a dentist for an act or conduct not defined in advance nor the power to define, in accordance with an unfettered discretion, the acts or conduct which would justify disciplinary action against a dentist.

Such unlimited power, continued the court, is not claimed by the board. It claims that whether an act or conduct of an accused dentist is "unprofessional" may be determined by the standards recognized by the dental profession as "ethical" and that the legislature may properly leave to a quasi-judicial body the task of ascertaining and applying those standards in a particular case. Hence the legislature, so it argues, has properly delegated to it power to define "ethical" professional standards and to adopt rules and regulations prohibiting acts or conduct which do not, in its opinion, conform to such standards. Acting in accordance with such a contention the board has adopted "regulations governing dental advertising" which, in effect, provide that stated forms of dental advertising are unprofessional. Among these is "employing or making use of advertising solicitors or free publicity press agents." These regulations are an attempt to define "ethical" professional standards. The specific supervisory powers of the board of regents over the practice of dentistry enable it, within reasonable limits, to prescribe canons by which conduct deemed by it, in the exercise of fair judgment, to be unprofessional and

objectionable may, in the interest of rescuing that profession from vulgar commercialism, be banned. The field in which that power may be exercised is nonetheless subject to restriction by the legislature, and the board of regents cannot by the exercise of that power enlarge on the causes set out in the act for which the license of a dentist may be revoked or suspended.

The court then referred to the fact that that section of the dental practice act enumerating causes for disciplinary action as it was originally enacted (Laws 1927, ch. 85) provided for disciplinary action in instances in which the accused dentist had "been guilty of unprofessional or immoral conduct," or of gross ignorance or inefficiency in his profession, "or of fraud or deceit in procuring admission to practice." The statute in that form, said the court, placed no restriction on the means of publicity or the form of advertising that a dentist might use, but the board of regents adopted regulations declaring that certain forms of advertising were improper and unprofessional and this court in *Matter of Dr. Bloom, Dentist, Inc. v. Cruise*, 259 N. Y. 358, 182 N. E. 16, approved the assumption of that power by the board of regents. Thereafter the legislature amended that particular section, adding as a specific cause for the disciplining of licensees "that the dentist is guilty of untrue, fraudulent, misleading or deceptive advertising." Regulations promulgated by the board purported to impose more drastic restrictions. Since the legislature had undertaken to impose a specific restriction on dental advertising, this court in *Brown v. University of State of New York*, 266 N. Y. 598, 195 N. E. 217, held that the board of regents could not adopt different or additional restrictions prohibiting the use of particular means of publicity, that the regulation of the board of regents was for that reason invalid and that the statute imposing specific restriction on advertising impliedly sanctioned advertising that did not violate the specific statutory restrictions. Thereafter, the legislature itself determined that the means of publicity which the board of regents had attempted to ban by regulation should, with some exceptions, be banned by statute and amended this particular section accordingly as it now reads, in effect, prohibiting advertising for patronage by means of hand bills, posters, circulars, stereopticon slides, motion pictures, radio or newspapers.

It should be noted, continued the court, that in *Brown v. University of State of New York*, supra, this court did not hold that the challenged rule or regulation of the board of regents was unreasonable. We did not question that in the exercise of the police power the state could place such a restriction on dental advertising. We held there, however, that the regulation of the board of regents was invalid only because the legislature having itself fixed a standard for dental advertising and having provided that failure to abide by such standard was ground for revocation of a license had by necessary implication sanctioned advertising which did not transgress the express ban of the statute and had not delegated to the board of regents power to provide other standards of permissible advertising or to create additional grounds for revocation of license. Though the legislature has thereafter by amendment of the statute placed a ban on the use of some of the means of advertising which the board of regents had attempted to ban by regulation, the ban is not complete with respect to all forms of advertising. The legislature has specifically banned advertising "for patronage by means of hand bills, posters, circulars, stereopticon slides, motion pictures, radio or newspapers." Publicity or advertising by other means is still impliedly sanctioned by the statute. The reasons which dictated the decision in *Brown v. University of State of New York* constrain the courts, with even more compelling force, to declare invalid any assumption by the board of regents, such as is here involved, to ban by rule or regulation such other means of publicity or advertising.

The board of regents, continued the court, cannot suspend or revoke the license of a dentist for any cause not specified in the dental practice act. It cannot ban as unprofessional conduct which has been impliedly sanctioned by the legislature. Nor can it by regulation ban, as unprofessional conduct which, though not expressly or impliedly sanctioned by the legislature, accords with the standards accepted

proper by the consensus of practitioners in that field. Even so there remains a large field in which the board of regents may by the exercise of its specific supervisory power prescribe canons by which conduct deemed by it in the exercise of fair judgment to be unprofessional and objectionable is banned. Though a breach of a regulation or canon prescribed by the board of regents is not of itself and in all cases sufficient ground for discipline it may be sufficient if the regulation or canon is reasonable and the conduct which has been specifically banned by the regulation may fairly be classed as unprofessional. The rule adopted by the board that the employing or making use of advertising solicitors or free publicity press agents constitutes unprofessional conduct may be invalid under *Brown v. University of State of New York* if the principles announced in that case were rigidly applied. However it must be considered that the employment and use of advertising solicitors and free publicity press agents are ordinarily for purposes and in a manner which would be regarded as unprofessional and improper and the dentur practice act should not be construed as an implied sanction of such employment or use. Nonetheless, there may be occasions when advertising solicitors or free publicity press agents may be employed or used for purposes and in a manner that could not reasonably be regarded as unprofessional and the board of regents cannot by general regulation ban proper use and improper use indiscriminately. The court apparently believed that under the circumstances Cherry's conduct in his connection with the credit service was not unprofessional and accordingly ordered in effect that the order of the board of regents suspending Cherry's license be set aside.—*Cherry v. Board of Regents of University of State of New York* 44 N. E. (2d) 405 (N. Y., 1942)

COMING MEETINGS

HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION CHICAGO BEGINNING JUNE 7. DR OLIN WEST 535 NORTH DEARBORN ST. CHICAGO SECRETARY

American Association of Genito-Urinary Surgeons Stockbridge Mass. June 10-12 Dr Charles C Higgins 2020 East 93d St. Cleveland Secretary

American Association of Industrial Physicians and Surgeons Rochester, N. Y. May 25-27 Dr E. C. Holmblad 28 East Jackson Blvd., Chicago Managing Director

American Association on Mental Deficiency New York May 12-15 Dr Neil A. Dayton Mansfield Training School Mansfield Depot Conn. Secretary

American College of Radiology Chicago June 6 Mr Mac F. Cahal, 540 North Michigan Blvd. Chicago Executive Secretary

American Gynecological Society Hershey Pa. May 31 June 2 Dr Howard C. Taylor Jr. 842 Park Ave. New York Secretary

American Ophthalmological Society Hot Springs Va., June 10-12 Dr Walter S. Atkinson 129 Clinton St. Watertown N. Y. Secretary

American Psychiatric Association Detroit May 10-13 Dr Winfred Overholser St. Elizabeth's Hospital Washington D. C. Secretary

American Psychoanalytic Association Detroit May 9-11 Dr Leo H. Bartemeier General Motors Bldg. Detroit Secretary

American Society of Clinical Pathologists Chicago June 4-6 Dr Alfred S. Giordano 531 North Main St. South Bend Ind. Secretary

American Surgical Association Cincinnati May 13-14 Dr Warfield M. Firor Johns Hopkins Hospital Baltimore Secretary

Connecticut State Medical Society New Haven May 25-27 Dr Creighton Barker 208 Church Street New Haven Secretary

Georgia Medical Association of Atlanta May 11-14 Dr Edgar D. Shanks 478 Peachtree St. N.E. Atlanta Secretary

Illinois State Medical Society Chicago May 18-20 Dr Harold M. Camp 224 South Main St. Monmouth Secretary

Massachusetts Medical Society Boston May 24-26 Dr Michael A. Tighe 8 Fenway Boston Secretary

Minnesota State Medical Association Minneapolis May 17-19 Dr B. B. Souster 493 Lowry Medical Arts Bldg. St. Paul Secretary

Mississippi State Medical Association Jackson May 11-13 Dr T. M. Dye Clarksdale Secretary

New Hampshire Medical Society Manchester May 11 Dr Carleton R. Metcalf 5 South State St. Concord Secretary

New Jersey Medical Society of Newark May 25-26 Dr Alfred Stahl 55 Lincoln Park Newark Secretary

North Carolina Medical Society of the State of Raleigh May 10-12 Dr Roscoe D. McMullan Red Springs Secretary

North Dakota State Medical Association Bismarck May 10-11 Dr L. W. Larson 221 Fifth Street Bismarck Secretary

Oklahoma State Medical Association Oklahoma City May 11-12 Dr Lewis J. Moorman 210 Plaza Court Bldg. Oklahoma City Secretary

Rhode Island Medical Society Providence June 2-3 Dr William P. Buffum 122 Waterman St. Providence Secretary

West Virginia Medical Association Charleston May 17-18 Mr Charles Lively 1031 Quarrier St. Charleston Executive Secretary

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fifth Annual Meeting Held at Chicago Nov. 6 and 7 1942

The President, Dr. ALFRED R. BARNES, Mayo Clinic, Rochester, Minn., Presiding

(Continued from page 10)

The Nature and Properties of Antirenin

Dr. HARRY GOLDBLATT, Yale; J. KATZ, Ph.D., Dr. HARVEY A. LEWIS, LEWIS RICHARDSON, A.B., A. GUERRA-ROJAS and Dr. IRENE GOTTMAN, Cleveland. The daily intramuscular injection into dogs of a small quantity (1 arbitrary unit) of active hog rennin for three to five months results in the development of a factor in the blood which prevents the pressor effect of a large dose (20 or more units) of hog rennin when it is injected intravenously into such dogs. The intravenous injection of hog rennin does not result in the development of antirenin in the serum. In our laboratory a unit of rennin is defined as the minimum quantity which will raise the direct mean femoral blood pressure of an anesthetized trained dog weighing between 10 and 20 Kg. by 30 mm. of mercury. To the effective substance in the blood Wakerlin and Johnson have given the name antirenin. The development of antirenin can be hastened by the administration of large quantities of rennin. The blood serum of such dogs is also capable of inactivating or destroying rennin 'in vitro' so that a mixture of rennin and antiserum does not produce the usual pressor effect when it is injected intravenously into normal dogs. We have found that the effect of rennin antiserum is virtually instantaneous both 'in vitro' and 'in vivo' and that the reaction does not require eighteen hours or more as first suggested by Wakerlin and Johnson. Hog rennin antiserum is effective both 'in vitro' and 'in vivo' against the rennin of other animals but not against human rennin. In dogs with the highest antirenin titer the intravenous injection of angiotonin (hypertensin) still continues to be as effective in raising the blood pressure as in normal animals. There is no increase in hypertensinase (angiotoninase or angiotonin inhibitor) in rennin antiserum. The prehypertensin level of rennin antiserum is equal to that of normal animals.

DISCUSSION

Dr. G. E. WAKERLIN, Chicago. We agree with Dr. Goldblatt that the 'in vitro' neutralization of rennin by antirenin occurs practically immediately. We prefer to use the etherized bilaterally nephrectomized dog for assaying rennin, although the unanesthetized dog is a satisfactory assay animal. The use of the term 'kidney cortex equivalent' may be somewhat ambiguous. However, as our rennin solutions are prepared by Dr. Johnson they are relatively constant in pressor activity, so that to us renal cortex equivalent has meaning. We also found that the development of antirenin depends on the amount and frequency of administration of rennin. It is interesting to note that in the rabbit antirenin can be produced by intravenous injections of rennin as we have shown but in the dog for some reason intravenous injections of rennin do not give rise to antirenin. The titer of antirenin will vary somewhat in different dogs. In our first therapeutic experiment 1 dog continued to show antirenin in his serum for a year after injections of hog rennin were stopped, although his blood pressure returned to the pretreatment hypertensive level four or five months after the discontinuance of treatment. We have treated 4 hypertensive dogs with a second course of partially purified hog rennin with good antirenin titers developing early but with no reduction in blood pressure until the dosage of partially purified hog rennin extract was doubled. In these experiments we also treated 1 hypertensive dog with highly purified hog rennin and another hypertensive animal with smaller doses of partially purified hog rennin without any decreases in blood pressure although antirenin in good titer developed early in treatment. We have treated a group of hypertensive dogs with large doses of highly purified hog rennin and have seen reductions in blood pressure somewhat less satisfactory than we have previously seen with smaller doses of partially purified hog rennin, suggesting that the antihypertensive activity is due to some constituent of the extract other than rennin. Although one of these animals treated

with highly purified hog rennin showed a satisfactory reduction in blood pressure early in treatment; no antirennin appeared in his serum until late in the course of therapy. We are also completing an experiment in which 2 out of 3 hypertensive dogs showed blood pressure reductions with large doses of heat inactivated hog rennin, although no antirennin ever appeared in their serums. In our prophylactic experiments we have also obtained evidence against antirennin being the mechanism involved in the successful prophylaxis of experimental renal hypertension. Thus prophylaxis apparently succeeded in 1 of the dogs given dog rennin and in 1 of the animals receiving heat inactivated hog rennin, although antirennin never appeared in their serums. Moreover, the dogs protected by hog rennin and by rabbit rennin have remained normotensive for many months after antirennin disappeared from their serums following treatment. In spite of these objections to the antirennin hypothesis, however, the therapeutic and prophylactic effects of partially purified hog rennin in experimental renal hypertension may be due to antirennin. We are now beginning a group of experiments which should go a long way toward determining whether antirennin is the mechanism, whether some other type of immune or antihormone response to rennin is involved or whether the antihypertensive activity is due to some constituent of the rennin solutions other than rennin.

DR. A. C. CORCORAN, Indianapolis. Human monkey and baboon rennins and rennin activators interact to yield angiotonin, while their rennin activators do not interact with other mammalian rennins. One might then suggest that rennins from one or the other of these species be used for studies of antirennin in human beings, monkeys and baboons. Our tentative use of the term 'rennin activator' was meant only to signify that in its absence rennin was inactive and when the reaction was shown to be enzymatic, the term was retained until the nature of the reaction was fully elucidated. Complete evidence that rennin, an enzyme, acts on alpha globulin as substrate will be presented by Drs. Plentl and Page. The so-called rennin activator is identical with alpha globulin and, as suggested by Page and Helmer to this group three years ago, is the substrate on which rennin acts to liberate angiotonin. With regard to the pyrogenicity of renal extracts used in the experimental treatment of arterial hypertension, Dr. Page and his associates have described their occurrence and course in some detail. These "nonspecific" reactions (I object to the term nonspecific for a mechanism which follows a predictable course of altered physiology) do not account for all the effects observed with the extracts, since their occurrence has not been of the daily or weekly character which occurs with injections of pyrogens such as typhoid vaccine. Such activity did participate in some of our results, but that we had accepted the wholly "nonspecific" activity of the extracts was not, I am sure, the impression that Dr. Goldblatt wished to convey.

DR. HARRY GOLDBLATT, Cleveland. Although Dr. Wakerlin insists that antirennin is not the factor responsible for the prevention and cure of experimental renal hypertension which can be accomplished by daily intramuscular injections of rennin, yet we are of the belief that our own experiments do definitely indicate this possibility. More work will have to be done to prove this important point. I can tell Dr. Corcoran that we are already using the Macaque monkey in our studies, but it is too early to report results.

Nature of Rennin Activator and the Reaction Between It and Rennin

DRS. ALBERT A. PLENTL and IRVINE H. PAGE, Indianapolis. Several years ago investigations conducted in the Lilly Clinic showed that rennin was vasoinactive unless allowed to interact with a globulin fraction of plasma with the formation of angiotonin. While several reasons were given for the thesis that the reaction was enzymatic in nature, no strict proof was presented that this was so. Braun-Menendez suggested the same thesis but also offered no strict proof. Such proof can be furnished only by a kinetic analysis.

Enzymatic reactions are the biologic counterparts of catalytic reactions, hence the catalyst (enzyme) does not take part directly in the reaction, yet its presence is essential for the reaction to occur. Such reactions must follow the course prescribed by a monomolecular reaction (first order reaction).

The action of rennin on rennin activator was studied and the reaction constant (velocity) found to be directly proportional to the rennin concentration. Plotting the logarithm of the concentration of the product (angiotonin) against time produces a straight line. These observations constitute proof that the reaction rigorously satisfies the requirements of a monomolecular reaction. Rennin is therefore the enzyme and rennin activator the substrate.

Rennin activator is usually obtained from the globulin fraction of hog or cow serum. Electrophoretic analysis of a representative sample indicated that it is a mixture of alpha, beta and gamma globulins and a small amount of albumin, its major constituent being alpha globulin (56 per cent). Repeated fractional precipitation of globulins within narrow limits of ammonium sulfate led to the isolation of each constituent in reasonably pure form. Incubation of rennin with beta and gamma globulins as well as albumin did not give any angiotonin, while alpha globulin gave twice as much as the original "rennin activator". The substance referred to as "rennin activator" is therefore identical with or has the same electrophoretic mobility as alpha globulin.

An appreciable quantity of angiotonase could be demonstrated in the albumin fraction, while none could be found in the globulins.

Mechanism of Auricular Paroxysmal Tachycardia

DRS. PAUL S. BARKER, FRANK N. WILSON and FRANKLIN D. JOHNSTON, Ann Arbor, Mich. Auricular paroxysmal tachycardia cannot readily be induced or studied in experimental animals. Speculations as to its nature must be based on pertinent observations on man. We wish to examine the evidence that this disorder is due to circus rhythm in the auricles, the path of which involves one of the specialized auricular nodes.

The available evidence suggests that somehow these nodes are involved in the abnormal mechanism. In all but 2 of 100 unselected cases the form of the auricular deflections was consistent with their origin in or near the auriculoventricular node or some part of the sinoauricular node. The slowing and termination of attacks by vagal stimulation and by digitalis are most logically explained by their effects on the nodes, as is the occasional acceleration of the rate by exercise. Furthermore, atrioventricular block is rare, especially in paroxysms arising in or near the auriculoventricular node.

That the abnormal mechanism is a circus rhythm is suggested by the abrupt onset and termination of attacks, by the remarkable stability of the rate, by the slowing and termination of attacks by quinidine and by the occasional alternation of cycle length.

Nevertheless the circus rhythm of auricular paroxysmal tachycardia must be of a special kind, different from that of auricular flutter and fibrillation. This is indicated by the slowing and termination of attacks by vagal stimulation and by digitalis, by the acceleration of the rate by exercise, by the relatively slow rate and long cycle length and by the separation of the auricular deflections by isoelectric intervals.

No one of these features of auricular paroxysmal tachycardia is of itself decisive, but all together point strongly toward circus rhythm involving one of the nodes. This mechanism alone can account adequately for the abrupt onset and termination of the paroxysms, the stability of the rate, the form of the auricular deflections and their separation by isoelectric intervals, the relatively slow rate and long cycle length, the occasional alternation of cycle length, the rarity of atrioventricular block and the impossibility of producing it in most cases, the acceleration of the rate by exercise, and the slowing and termination of attacks by vagal stimulation, digitalis and quinidine.

DISCUSSION

DR. G. E. WAKERLIN, Chicago. From a physiologic standpoint the vagus is relatively insensitive to direct pressure. When one speaks of stimulation of the vagus by pressure in man one really means stimulation of the carotid sinus with reflex increase in the inhibitory effects of the vagus.

DR. PAUL S. BARKER, Ann Arbor, Mich. I used the term "vagal stimulation" for brevity.

Syphilis of Central Nervous System—Marsh has tried to find some of the reasons for the frequent discrepancy between the clinical and pathologic diagnosis of 115 verified cases of neurosyphilis at the Los Angeles County Hospital. The 115 cases were collected from the protocols of 25,000 necropsies. The most common errors in diagnosis were due to (1) incomplete study of the patient because of sudden death soon after admission (2) failure to recognize the minimal signs of chronic meningitis (3) the tendency to call all cases of neurosyphilis syphilis of the central nervous system, "C. N. S. lues," with no effort at accurate classification and (4) inaccurate classification of well defined cases of neurosyphilis. A review of the serologic reactions of the group revealed that all but 1 patient with dementia paralytica had positive blood and spinal fluid Wassermann reactions, in this 1 the reaction was anti-complementary. The colloidal benzoin reactions were typically paretic in each instance. Of the 37 patients who had tabes dorsalis and who had had serologic reactions performed, 14 had a negative blood Wassermann reaction and 7 a negative spinal fluid Wassermann reaction. Of the 22 who had had the colloidal benzoin test done only 8 had a typical tabetic curve. In 60 of the 80 with meningovascular syphilis a positive blood Wassermann reaction was recorded, while the spinal fluid Wassermann reaction of 43 was recorded as positive. The colloidal benzoin curve of only 22 was typically meningitic. The various types of neurosyphilis are proved pathologically to be fairly clearcut entities. The chief exception is chronic meningitis, which obviously may produce few changes easily overlooked. The diagnosis of combined types of neurosyphilis such as tabes with dementia paralytica usually proves to be erroneous. Its widespread symptoms are due to multiple vascular lesions or to a syphilitic entity plus some other disease, usually arteriosclerosis. The objective of a refined diagnosis is more worthy of scientific medicine and more productive of intelligent effort at therapy than the noncommittal and indefinite designation of "C. N. S. lues."

- *First Aid in Chemical Warfare R. C. Holcomb, Upper Darby, Pa.—p. 1

First Aid in Chemical Warfare—The twenty warring chemicals that the Medical Division of the Office of Civilian Defense considers are subdivided into seven classes: lung irritants, blister gases, tear gases, irritant smokes, incendiaries, screening smokes and systemic poisons. An ideal protective ointment against vesicants is known as Protective Ointment MIV by the Chemical Warfare Service, but it is not apt to be available for civilian use. Of the neutralizing agents, bleach powder has been used successfully, but as it is not always available the ideal is to cleanse the skin thoroughly with soap and water. Bleaching solutions of sodium hypochlorite have been suggested when other preparations are not readily available in an emergency. For lewisite the neutralizing agent is an 8 per cent solution of hydrogen peroxide, but the U. S. P. 3 per cent solution may be used when the stronger and more preferable one is not available. Some of the solvents recommended are nonleaded gasoline, alcohol, kerosene and carbon tetrachloride (pyrene). The irritant must not be spread by an excess of the solvent. Of the detergents soap will mechanically remove vesicants from the skin. Holcomb also lists first aid treatment for the other agents.

Riboflavin and Niacin Deficiency—To determine the frequency of vitamin deficiency in medical diseases, Goldsmith studied 200 patients admitted to the medical wards of Charity Hospital, there were 50 each of white and Negro males and females whose ages varied from 5 to 82 years. The clinical criteria for suspecting niacin and riboflavin deficiency were those suggested by the Subcommittee on Medical Nutrition, Division of the Medical Sciences, National Research Council. Forty per cent of the patients showed definite and 67 per cent probable evidence of deficiency of niacin and/or riboflavin. Changes in the tongue were the most common abnormal signs, while lesions of the skin, eyes and lips occurred in this order of frequency. Severe and characteristic manifestations were present more often in white than in Negro patients. Signs of deficiency were present in all persons with hyperthyroidism, cirrhosis of the liver and chronic alcoholism, and in two thirds or more of those who had infections, diabetes mellitus, carcinoma and diseases of the gastrointestinal tract. Inadequacy of riboflavin was the most frequent cause of deficiency disease. The high incidence of deficiency was not surprising, as most of the persons examined had been living on an inadequate diet for months or years, either because of poverty or because of poor food habits. With the onset of disease their insufficient intake of vitamins did not supply the minimal requirements. Many patients had evidence of deficiency of vitamin A and ascorbic acid, as well as of the vitamin B complex.

Intravenous Use of Digitalis Glycosides—LaDue gave 83 patients (62 with auricular fibrillation and 21 with regular sinus rhythm) with heart failure consequent to valvular disease, hypertension or arteriosclerosis lanatoside C by vein, and 85 patients (40 with auricular fibrillation and 45 with regular sinus rhythm) took the drug orally. All the patients were given "digitalizing" and maintenance doses. There was no statistically significant difference in either group in the average rate of improvement as measured by a fall in venous pressure and circulation time, a rise in vital capacity and diuresis. Within two hours of an intravenous injection of 16 mg. of lanatoside C, 10 patients with congestive heart failure with regular sinus rhythm responded with a decrease in the diastolic heart volume and an increase in the stroke output, minute output and work of the heart, therefore the mechanical efficiency of their hearts was increased. Lanatoside C intravenously is recommended in uncomplicated, severe congestive heart failure. It is a safe and effective way to achieve rapid digitalization.

Prognosis in Civilian Head Injuries—In addition to the organic damage the prognosis of accidents depends on economic, social and psychologic factors which profoundly influence the patient's health, happiness and working capacity after an accident. Among 300 consecutive admissions of head injury there were 255 civilians available for study. The accidents were mainly road accidents of a mixed urban and rural area. Ten of the 255 patients died and 2 were permanently incapacitated as the result of cerebral damage. More than 80 per cent of patients were discharged from the hospital within two weeks of admission. All who stayed in the hospital four weeks or longer did so because of fractures. The average working time lost by wage earners was eight weeks. In those with a post-traumatic amnesia of one hour or less the average working time lost was four to five weeks, in those with post-traumatic amnesia of one to twenty-four hours it was five to six weeks, in those with post-traumatic amnesia of one to seven days about nine weeks and in the severest cases it was fourteen weeks. Eight patients were off from work for twenty-six weeks, 2 because of cerebral damage. With the exception of those with cerebral damage, it could be shown that patients who stayed away from work for an unusually long time did so for social and psychologic reasons rather than because of the physical effect of the accident. The results emphasize the need for prophylactic management and after-care until the patient has returned to full time work.

Crush or Compression of Limbs and Renal Impairment—A classification depending on the history and the relevant detail of crush injury or compression is adopted by Shepherd, who divides such injuries into three types (1) com-

pression of a limb or limbs in a homogeneous manner by loose rubble or other debris (2) pinning of a part or parts of a limb or limbs by localized pressure and (3) mixed compression by rubble, masonry and timbers involving various parts of the body. Recognition of the mode of injury will give some guide to a rational therapy. 'Compression syndrome' rather than 'crush syndrome' should be reserved for cases in which typical local lesions and secondary renal effects develop. The first type of damage with immediate or prolonged effects, is due to prolonged ischaemia of the limb. Elevation of the limb after bandaging and then gradual release of the supporting bandage should result in a gradual return of circulation. Surgical intervention (amputation) is not necessary unless definite and extreme tenderness of muscle compartments exists when multiple tension relieving incisions are indicated. It is doubtful whether peripheral edema can be reduced by concentrated serum given intravenously. Inhalation of oxygen is worth trying in the early stages; it may help to counteract the local anoxic effects. The local treatment of group 2 cases is the same, except that when acute ischaemia is not explained by the tension of edema the main artery should be explored and freed. Arterial spasm from local injury is likely to be a feature. In group 1 and 2 cases the danger of renal injury is proportionate to the local injury, dehydration and prolonged low blood pressure. The two latter factors must be corrected. If the circulation is impaired seriously the transfusion of plasma and oxygen therapy must be intensive. Plasma should be reserved for patients with true haemoconcentration and diminished blood volume; it may harm other patients. With renal impairment or after plasma transfusion excretion is best assured by the slow infusion of isotonic sodium sulfate. The effect of toxins may be diminished by rapid and adequate renal secretion. Drastic diuresis is to be avoided. Blood transfusion is contraindicated. In the third group specific local treatment is a secondary consideration, as the lesions are numerous and varied. Gross dehydration and its associated acidosis require immediate attention. With these patients extreme starvation and physical exhaustion have been added to the effects of trauma. The fact that they have reached the hospital alive suggests that the organism has adapted itself at least temporarily, to a low and disordered metabolism and normality can be reached only gradually. Overheating must be avoided and fluid loss must be made up slowly, if possible by mouth or by rectal or intravenous therapy. Protein intravenously is to be avoided, alternate dextrose saline and sodium sulfate is preferable. The chief cause of renal failure in these patients is acidosis, and its gradual correction will control the associated uremia. The danger of pulmonary edema because of prolonged intravenous therapy when a blast lesion of the lungs is present must be risked, oxygen therapy may help to control such effects. Convalescence is protracted.

Suggestion for Treatment of Allergic Conditions—

Suranyi points out that the oral administration of nicotine acid amide produces in some cases erythema of extensive areas, a feeling of heat and itching, that is symptoms similar to those elicited by the parenteral administration of histamine. The toxin involved in allergic reactions has sometimes been identified as a histamine like substance and on this basis therapeutic methods have been suggested which involve histamine and decomposition of histamine. The similarity between histamine action and the effect of nicotine acid suggested to the author the possibility of using nicotine acid in children with allergic disorders. He gave a number of allergic children three weeks of treatment, giving twice daily, between meals, 0.025 or 0.05 Gm. of nicotine acid, depending on the age. The treatment was instituted only in those cases in which an oral nicotine acid test resulted in erythema. Urticaria, asthma and spastic bronchitis were found to respond favorably, exudative eczema was influenced slightly less.

Reinfusion of Blood in Abdominal Cavity—Anderes and Laszczower developed a method of reinfusing blood in the abdominal cavity which does not interfere with the surgeon's chief task, that is, rapid hemostasis by clamping of the tube. The blood is withdrawn from the abdomen by means of a suction pump, and by means of a specially constructed filter it is drawn directly into the transfusion tube. In this way not only is handling and air contact avoided but the danger of secondary infection is reduced. After illustrating and describing the apparatus and its use, the authors say that so far they have used it in 15 cases. The results were always favorable. The advantages of reinfusion having been stressed by other investigators, the authors do not repeat them. In the cases in which reinfusion is not possible on account of excessive coagulation, inflammation of the abdominal organs or overaged blood (hematocle) the authors prefer the transfusion of donor blood.

 Malherbe's Epithelioma W. F. Muehlon —p 53
 Cavernous Hemangioma of Ovary H. Ackermann —p 79
 Organ Specificity of Renal Extracts P. Kallos —p 119

Tissue Reactions to Thorotrast—Wohlwill examined 38 human cadavers, 8 extirpated cerebral tumors and 3 other excisions for the effects of the diagnostic injection of thorotrast. The description of his observations is illustrated with photomicrographs. The direct effect of undiluted thorotrast solution for instance in mammography and ventriculography is local retention accompanied by necrosis and various inflammatory reactions. Following intra-arterial injection thorotrast first accumulates within the capillary lumens, then it migrates through the walls and finally it is deposited in the perivascular tissues. In the reticuloendothelial system thorotrast is first diffusely stored, particularly in Kupffer's star shaped cells, later it is taken up by the symplasmatic cell group situated in the portobiliary centers of the liver. Thorotrast is stored by the tumor cells of meningiomas and neurinomas. The histologic reactions are largely dependent on the amount and the concentration of the injected thorotrast.

 Epilepsy with Frontal Focus with Rare Symptoms V. Gilsanz Garcia —p 109
 Thrombopenic Purpura Due to Ingestion of "Sedormil" J. Pelaez Redondo —p 324

"Hunger Edema"—Jimenez Diaz and his collaborators observed several cases of general denutrition with edema and diarrhea, the so called hunger edema which occurred during the Spanish war and immediately afterward. The disease was due to dietary deficiency in all cases. The authors review the clinical symptoms and the course of the disease which develops in three periods. The main symptoms are progressive asthenia, anorexia, progressive emaciation, increased thirst, polyuria, frequent fainting, diminished body temperature, bradycardia, arterial hypotension, edema, diarrhea, atrophy of the skin, paresthesia in the limbs and pigmentation of the hands, legs and face. The velocity of sedimentation of the erythrocytes is high and the figures of total proteins in the plasma are diminished. The symptoms are mild during the first period of the disease. The appetite for food is moderate. Edema and diarrhea appear in the second period, which begins with acute attacks of fever, diarrhea and edema either simultaneously or in succession. Edema begins suddenly in the lower limbs. Later on it appears in the face, the hands, the arms, the abdomen and the thorax. Sometimes it grows to true anasarca. Diarrhea is abundant and liquid. In rare cases there are discharges of mucus and blood and it is associated with colic pain. Symptoms of the disease, especially asthenia and emaciation, become acute. Lack of appetite, dryness and inflammation of the buccal and pharyngeal mucosae and, later on, glossitis, pharyngitis and ulcerous stomatitis appear. The "black tongue" is observed in some cases. During this period the subcutaneous tissue disappears and the muscular tissue diminishes in more than 40 per cent of its volume. The skin wrinkles. Parasitic diseases, especially scabies, are frequent and folliculitis, multiple cold abscesses, chronic ulcers, pilar keratosis and impetigo appear. The patients have a tendency to develop acute diseases from latent ones, such as for instance acute pulmonary tuberculosis. Diseases of the respiratory tract and local and general infections are followed by acute complications. The third and last period of the disease is complicated by intractable vomiting, tympanites, somnolence and final peripheral collapse, coma or acute convulsions. The treatment consists of rest in bed and progressive feeding with diets in which the number of calories and the amount of proteins (milk, cheese, eggs and meat) are gradually and slowly increased. Patients in the first period of the disease rapidly improve, but the recurrences are frequent unless the disease is controlled by administration of a proper diet during more than three months. Patients in the second period show sudden disappearance of edema when they are put to bed. The general symptoms improve in some cases very slowly. The diet should be carefully controlled and administered for as long as polyuria and rapid sedimentation of the erythrocytes persist. Blood transfusion or plasma injections are indicated in cases of acute edema and when the figures of proteinemia are very low. A large number of patients who are observed in the second period of the disease and all those who are seen in the last period die. Death may be due to aggravation of a latent disease (pulmonary tuberculosis), an intercurrent disease, acute complications of the cutaneous, buccal and pharyngeal diseases or general cachexia. In the last event it may occur with sudden collapse or else with either acute edema of the lung or violent convulsion in rare cases, and with coma and slow peripheral collapse in the majority of the cases. General denutrition of the muscular tissues and moderate diminution of the size and weight of the viscera are the only findings during necropsies on cadavers of patients who died from "hunger edema" without complications. The diminution of the size and weight of the viscera, in order of frequency, is as follows: kidneys, liver, pancreas, spleen and heart. The heart has the aspect of the heart in brown atrophy. The other viscera are pale but otherwise normal.

Book Notices

Reel Library By Charles C Higgins MD Cleveland Ohio
Cleveland Ohio Fabricated Like 5" 1p 110 with 18 illustrations
Strickland Illinois & Baltimore Charles C Thomas 143

In this volume the author presents the results of ten years' study of the etiology and treatment of renal lithiasis. Seventy of the one hundred and twenty pages are devoted to etiology. The relationship between the formation of stone and the absence of certain essentials in the diet has been noted by many observers and is duly considered. The results of the author's experiments in the production and cure of stones are presented in great detail so that any one interested has immediate access to this information without extensive search through the literature. Although most of the text is devoted to this phase of the subject other factors in the etiology including the subject of renal calculi due to salicyluridine are also given. Symptoms and diagnosis are well presented. The author stresses the importance of careful and complete preoperative study by roentgen-ray, pyelography, functional tests and bacteriologic examinations of the urine. The surgical treatment is brief, to the point and well illustrated. As one might expect in a book of this type a detailed presentation of the dietetic treatment is given. Sixteen pages are devoted to diets, so that those interested in prescribing a suitable diet can do so with great ease. Unfortunately, one misses a chapter on pathologic changes due to renal stone. In his preface the author states: 'I hope to have prepared this little volume in such a way as to make it a quickly and easily accessible reference work for both the student and the established urological surgeon.' In this he has succeeded.

The Kenny Treatment for Infantile Paralysis An Orthopaedic Report
and Comparison of Results on Forty Eight Cases Treated by This Method
By Robert Dingham M.D. Captain Medical Corps Army of the United
States Board 1p 50 Camp Van Dorn Mississippi The Author.
[n d]

An orthopedist's attempt to evaluate the Kenny treatment of infantile paralysis from a study of practical and measurable end results forms the basis for a study of 60 cases of the disease. These have been divided for the purpose of comparison into three groups, those having received only the conventional or orthodox treatment, those receiving a period of orthodox treatment superseded by Kenny treatment and those receiving Kenny treatment from the outset of therapy. The study was based on the symptoms described by Miss Kenny viz muscular spasm, alienation and incoordination, rather than purely on muscle paralysis as in the past. The results indicate that treatment of these conditions will reduce the disability from the disease. The study brings out that the patients treated with the Kenny technique prove to have less residual paralysis and better functional use of retained muscles, show fewer deformities, and required fewer braces and surgical procedures than those treated by the orthodox methods or than those treated by the orthodox plus the Kenny method. Control cases of infantile paralysis are difficult because of the wide variation in the involvement of individuals afflicted. Estimation of the value of a clinical procedure can for the present be based only on impressions gained by those accustomed to dealing with the after effects of this disease. Dr Bingham's study represents a sincere attempt to evaluate the Kenny methods.

Victory Over Fear By John Dollard Cloth Price \$2 Pp 213
New York Reynal & Hitchcock 1942

"Some people hit upon the art of conquering fear early in life. Others never learn." Perhaps it is strange that man should have begun to learn about fear only in the past two generations. Yet every physician knows that anxiety, apprehension and restlessness are characteristics which frequently make or break the entire lives of many a man and woman. Dr. Dollard, who is a member of the staff of the Institute of Human Relations of Yale University, classifies seven deadly fears as basic; these are the fears of failure, sex, self defense, trusting others, thinking, speaking and being alone. One need not necessarily be equally afraid of all these at one time or perhaps of any one of them all the time, yet there is probably no human

being who has not at one time or another had one of these fears in some proportion. For any one with ordinary intelligence, victory over fear will be aided by a careful study of this book. It is full of important practical advice based on studies of actual cases which are related in interesting form. The book is dependent on the Freudian approach but does not have the Freudian atmosphere. Especially interesting is the chapter on security a subject already discussed by many other psychologists and also by the psychiatrists. While it is true that feelings of inferiority and anxiety are more or less the opposite of feelings of security there is something to be said for the importance of the fear of insecurity as in incentive. 'Every one is more afraid today than he was a year ago.' Yet the fear of death has always been with us and we can consider that fear today in the light of the great advances in medical science which make less threatening the possibility and more comfortable the approach. 'The long shadow of social change is falling on our society. Many people fear this change. Social changes are inevitable. Yet incentive has always depended on finding a reward for great striving. The fear of change inhibits progress. Most important is intelligent analysis of the need for change and correct guidance so that the trend may not destroy values which should be conserved.'

Regional Analgesia for Intra Abdominal Surgery With Special Reference to Amethocaine Hydrochloride By Norman R James FRCS & S D A Cloth Price 1p 57 with 20 Illustrations London J & A Churchill Ltd 1913

This monograph describes lucidly and in detail the author's technique of analgesia for upper abdominal operations for patients who are seriously ill. The method is reminiscent of that published by Bartlett (R. W. *Bilateral Intercostal Nerve Block for Upper Abdominal Surgery*, *Surg. Gynec. & Obs.* 71: 194 [Aug.] 1940) although several modifications are utilized. In the lateral position the sixth to twelfth intercostal nerves are blocked on each side by an injection of 1:1,000 concentration of pontocaine below the rib at a point 4 fingerbreadths from the vertebral spines. Then a posterior splanchnic block with 1:2,000 concentration of pontocaine is performed with the patient in the same position. The author recommends the use of carefully individualized doses of opiates given intravenously. Doses of omnopon varying from $\frac{1}{3}$ to $1\frac{1}{3}$ grains (0.02 to 0.10 Gm.) or morphine $\frac{1}{4}$ to $\frac{3}{4}$ grain (0.01 to 0.05 Gm.) are suggested. One may question whether the method described creates a lesser hazard than the methods which it is designed to supplant in "poor risk" patients namely profound inhalation or "high" spinal anesthesia. Several authors have deplored the confusion in nomenclature arising from taking over foreign patents. The local agent described in this book is marketed in the United States as pontocaine. It was introduced in Germany as pantocain, later marketed in other countries as decicain, tetracaine and butethanol, and is referred to by James as amethocaine hydrochloride, which is now available to him from a British manufacturer as anethaine.

Diseases of the Skin By Oliver S. Ormsby, M.D., Rush Professor of Dermatology, University of Illinois Chicago, and Hamilton Montgomery, M.D., M.S., Associate Professor of Dermatology and Syphilology, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, Rochester. Sixth edition. Cloth. Price \$14. Pp 1360 with 660 illustrations. Philadelphia: Lea & Febiger, 1943.

This is actually the latest descendant of the original Montgomery and Hyde textbook of diseases of the skin. This volume apparently completes a cycle, since a descendant of the original Montgomery is now the associate author. The book is reliable and authoritative. Its form has tended to become a model for works of a similar character.

The introductory section constitutes a manual of something over a hundred pages giving a general discussion of the anatomy and physiology of the skin and the general symptomatology, etiology, pathology diagnosis prognosis and therapy of skin diseases. Then come the sections covering skin diseases in various classifications, such as the hyperemias, hemorrhages, hypertrophies, atrophies pigmentary disturbances, metabolic disorders tumors, specific inflammations, neuroses, parasitic diseases and conditions affecting the sweat glands, the hair, the nails and the mucous membranes. A study of the table of con-

tuation of hypertension or albuminuria with fluid retention, with or without symptoms, occurring only in the latter half of pregnancy and subsiding before or soon after delivery. From a clinical, pathologic and laboratory standpoint, this vascular syndrome which was superimposed on a previous hypertension is indistinguishable from the preeclampsia and the eclampsia occurring in patients whose blood pressure and urine were normal before pregnancy. We have called this condition toxemia superimposed on prepregnant hypertension. This condition has been referred to by other authors as "nephritic toxemia," "chronic nephritis," "essential hypertension," "vascular renal disease" and, in its less severe phases, "low reserve kidney," "kidney of pregnancy" and so forth. The clinical course of a patient with toxemia superimposed on prepregnant hypertension is represented in figure 3.

Figure 4 illustrates diagrammatically the various types of hypertension which occur during pregnancy. On rare occasions other types of hypertension may by coincidence have their onset during pregnancy, in which case they resemble the same disease as it occurs in nonpregnant patients. The most striking example of this is acute glomerulonephritis. Because of its rarity, it will not be discussed further.

DEFINITION OF TOXEMIA OF PREGNANCY

The hypertensive toxemia of pregnancy (preeclampsia and eclampsia) may be defined as the appearance in the latter half of pregnancy of (a) an abnormal elevation of blood pressure above the prepregnant level (regardless of the presence or absence of hypertensive disease before the onset of pregnancy) or (b) an increase above the prepregnant level of albumin in the urine in the absence of other obvious cause, (c) gen-

A significant increase above preexisting levels in the second half of pregnancy is the basic characteristic. The desirability of obtaining blood pressures and urinalyses before, during the first half and during the second half of pregnancy is apparent.

Fig 2 (M C)—Clinical course of hypertension uninfluenced by pregnancy. Despite a severe hypertension before pregnancy, no aggravation occurred during pregnancy or for at least seven months post partum.

CHARACTERISTICS OF TOXEMIA OF PREGNANCY

From the foregoing discussion it is apparent that toxemia of pregnancy is an acute vascular disease entity resembling closely acute glomerulonephritis in its clinical characteristics. Etiologically and pathologically the two diseases differ. The most important factors predisposing to the development of toxemia are hypertensive vascular disease of any cause or any degree of severity and the generalized edema of pregnancy. In our study toxemia developed in approximately one half of those with hypertension before pregnancy. We were unable to predict before its actual onset the hypertensive patients in whom toxemia would develop. It was our impression, however, that those with a low renal reserve or with malignant hypertension were especially prone to it. Generalized edema in pregnancy is usually unaccompanied by toxemia. The onset of toxemia, however, is nearly always characterized by the development of edema or its accentuation. The relation of the vascular manifestations to salt and water retention is striking, as Strauss⁷ has demonstrated experimentally, although in the absence of toxemia edema is rarely significant. It should be emphasized, however, that the basis of therapy of toxemia of pregnancy rests on elimination of this retained fluid. Without diuresis, improvement rarely takes place. Less important factors, predisposing to toxemia are primiparity,⁸ diabetes,⁹ twin pregnancies¹⁰ and perhaps hydatidiform moles.¹¹

Fig 1 (C McG)—Clinical course of preeclampsia. The patient had normal blood pressure and urine until the thirty-first week of pregnancy, when hypertension, albuminuria and generalized edema appeared. Under treatment, some improvement occurred before delivery, and post partum all abnormalities subsided rapidly except that some albuminuria persisted for at least ten months.

eralized edema in association with the foregoing in the majority of cases, and (d) a rapid diminution of these abnormalities before or soon after delivery. Symptoms may or may not be present.

Elevation of blood pressure and albuminuria do not, therefore, necessarily indicate that toxemia is present.

7 Strauss, M B. Observations on the Etiology of the Toxemia of Pregnancy. II. Production of Acute Exacerbation of Toxemia by Sodium Salts in Pregnant Women with Hypoproteinemia, *Am J M Sc* 194 772 (Dec.) 1937.

11 Page¹⁰ Stander¹⁰ Irving¹⁰.

Toxemia is peculiar to the second half of pregnancy, the average time of onset in our patients being at the thirty-fourth week. We have assumed that the hypertension and albuminuria are manifestations of the same underlying process, i. e. a vascular disease. The symptoms of toxemia of pregnancy like those of acute glomerulonephritis appear to result from a combination of fluid retention and hypertension. In the absence of either one symptoms are uncommon or if they are present, they are usually mild. When both are present however, cerebral symptoms frequently appear and consist of frontal headaches, scotomas blurred vision and blindness with or without demonstrable changes in the eyegrounds, nausea, vomiting, abdominal pain lassitude drowsiness twitching coma convulsions and a variety of bizarre neurologic manifestations. As in acute nephritis, symptomatic improvement follows diuresis. Physical examination of the patient with toxemia of pregnancy usually reveals a puffy face and hands. There is a striking absence of crepitations unless cardiac failure supervenes. The eyegrounds are usually normal, although in the more advanced stages of the disease there may be papilledema retinal detachment, hemorrhages and exudates. Spasm of the retinal arterioles have been described.¹² The heart is usually normal when toxemia is mild, but severe toxemia with pronounced generalized edema is frequently associated with manifestations of cardiac insufficiency. The liver is not enlarged as a result of toxemia. When palpable it indicates independent disease or cardiac failure.

Patients may improve spontaneously or as a result of therapy before delivery or within twelve to twenty-four hours after delivery. The first definite sign of

to its initial level within a few hours and at other times falling slowly over a period of days, weeks or, in rare instances, months. Albuminuria gradually diminishes over the course of days or weeks. Until diuresis has occurred, the patient may become worse

FIG. 4—Schematic representation of the clinical course of normal and hypertensive patients during pregnancy.

In our experience, postpartum eclampsia always occurs before diuresis is well under way, i. e. before seventy-two hours after delivery. All instances of coma and convulsions observed by us after this time have invariably been attributable to some other puerperal complication.

LABORATORY STUDIES

Our observations have indicated that capillary and venous pressures, circulation time (cyanide method), basal metabolic rate and liver function tests (icteric index, Takata-Arr test and bromsulphalein test) are essentially the same in toxemia as in normal pregnancy, except in cases of eclampsia, in which certain abnormal findings were occasionally found, as might be expected in a state which is nearly terminal. Capillary permeability to proteins was found to be normal, as indicated by a protein content of less than 0.3 Gm per hundred cubic centimeters in edema fluid. With 2 exceptions, there were no electrocardiographic changes in toxemia. There are essentially normal values for nonprotein nitrogen, blood urea nitrogen, carbon dioxide combining power, chlorides,¹³ sodium,¹⁴ blood sugar¹⁵ and blood calcium.¹⁶ Blood uric acid is frequently elevated in the mild and almost always in the severe cases.¹⁷ In eclampsia, in which the organism is in a state of disruption, striking changes in blood chemistry may occur, but these abnormalities have been considered a result rather than the cause of the syndrome.¹⁷ While the plasma proteins are usually lower in toxemia than in

Fig 3 (M W)—Clinical course of preeclampsia superimposed on prepregnant hypertension. Severe hypertension was present before and during the first twenty-two weeks of pregnancy. At the twenty-third week pronounced elevation of blood pressure, copious albuminuria and massive generalized edema appeared together with drowsiness and headaches. These abnormalities subsided rapidly after delivery.

improvement is diuresis and loss of edema, concomitant with which symptoms disappear rapidly. The blood pressure falls slowly or abruptly, at times returning

normal pregnancy, this is an inconstant finding even in the presence of pronounced generalized edema.¹

The significance of albumin in the urine has been emphasized. Addison's counts¹⁸ reveal a slight increase in the number of erythrocytes, white cells and casts of all sorts. Microscopic hematuria in the sediment centrifuged in the usual way is rare except in cases of eclampsia. Their presence in considerable numbers suggests the possibility of acute glomerulonephritis. Casts are common. Pyelonephritis recently emphasized by Peters¹⁹ was an uncommon finding in our cases.

Although renal function as indicated by our use of the urea clearance test at times showed a depression of function in the acute stages of severe toxemia this was not a regular finding. This is in keeping with observations by others.²⁰ Recent studies of renal clearances in several laboratories²¹ have indicated that during the acute phase of toxemia the renal blood flow is normal and the glomerular filtration is decreased. This change has been attributed to the thickened basement membrane of the glomerulus or to spasm of the afferent arteriole of the glomerulus.

Fig. 3 (C. H.)—Clinical course of post-toxic hypertension. Previous to pregnancy in 1929 blood pressure and urine were normal. Toxemia appeared in the twentieth week and persisted until the thirtieth week at which time labor was induced. Post partum a low grade hypertension persisted and became progressively more severe after 1937. A renal biopsy at the time of sympathectomy by Dr. Reginald Smith in 1941 revealed idiopathic nephrosclerosis.

Blood guanidine is not uniformly elevated in toxemia and when it is it follows rather than precedes the rise in blood pressure.²² The present status of the role

played in toxemia of the anterior and posterior pituitary hormones thyroid and ovaries has been reviewed elsewhere.¹ Although indirect evidence is suggestive that an endocrine abnormality exists and may ultimately be demonstrated to be responsible for the disturbance in water metabolism and in the vascular system, too little is known of the state of the endocrine system in toxemia at the present time to come to any definite conclusions concerning the role it may play in its production. To our knowledge, the excretion of adrenal cortical hormones has not been studied in toxemia.

Thus the laboratory has as yet yielded little insight into the actual mechanism and etiology of toxemia of pregnancy. The eternal search for some toxin from which the syndrome derives its name, has shed little light on the disorder.

SIGNAL

A high incidence of spontaneous prematurity, still births and neonatal deaths occurs in toxemia of pregnancy. In preeclampsia without preceding hypertension the fetal mortality has been reported to vary between 5 per cent in the mild and 25 per cent in the severe cases,²³ while in those with preexistent hypertension it has varied from 12 per cent in the mild to 69 per cent in the severe.²⁴ The studies of Neugearten²⁵ and Tyson and Bowman²⁶ showed that provided the fetus successfully survived the neonatal period there were no demonstrable ill effects later from preeclampsia and eclampsia. We did not detect hypertension or water retention in the newborn babies of toxemic and edematous mothers.¹

The maternal mortality from preeclampsia is but a fraction of 1 per cent in most series that have been reported.²⁷ In eclampsia, the maternal mortality varies greatly from clinic to clinic but it approximates 26 per cent in the country at large.²⁸

The late effects of toxemia of pregnancy on the mother have received the attention of only a few observers but merit emphasis. The careful follow-up studies of Herrick and Tillman,²⁹ Dieckmann and Brown,³⁰ Reid and Teel,³¹ and others indicate that approximately 25 per cent of those with normal prepregnant blood pressure who develop toxemia during pregnancy are left with a permanent postpartum hypertension. It is also recognized³² that a similar percentage of hyper-

tensive patients who develop toxemia during pregnancy have a higher blood pressure and more albumin in the urine after their pathologic pregnancy than before which again emphasizes the permanently harmful action of toxemia on the mother.

In a careful follow-up study, Reid and Icel¹¹ found that permanent vascular disease developed with far greater frequency in those whose toxemias had been mild than in those who had had eclampsia. From our own observations we are in accord with their conclusions. It appears that the duration of the vascular disorder during pregnancy is of greater importance than its severity in giving rise to permanent vascular disease. We have advocated termination of pregnancy after three weeks of conservative therapy of toxemia in order to avoid this late vascular damage. For the same reason Peckham³ has recently suggested terminating pregnancy after a toxemia of four weeks duration.

Although after a toxemic pregnancy hypertension and albuminuria usually disappear within a few days or a few weeks, they may persist for as long as a year and then disappear permanently. Such cases are not rare. These cases merge imperceptibly into those in which the hypertension or albuminuria are permanent. The course is then one of chronic progression indistinguishable from other types of chronic hypertensive disease such as chronic glomerulonephritis or benign or malignant essential hypertension. Figure 5 is illustrative of a typical case of post-toxemic hypertensive vascular disease. Elsewhere we¹⁶ have discussed in detail the clinical course of post-toxemic hypertension.

HISTOPATHOLOGY OF TOXEMIA OF PREGNANCY

In toxemia the main morphologic changes occur in the kidney, liver and placenta, although inconstant changes have been observed in many other organs.

The earliest changes in toxemia occur in the kidney rather than in the liver, as is usually stated. Renal lesions are diffuse and are primarily degenerative in character. The term glomerulonephrosis which has been applied to this condition by Fahr³⁷ would seem the most suitable. The epithelial cells of the convoluted tubules are swollen and contain numerous hyaline droplets. Varying amounts of fat are present. The epithelium of the glomerular tufts shows degenerative changes similar to that of the tubular epithelium. The basement membrane of the tufts is thickened to a variable degree owing to reduplication. The glomerular capillaries appear bloodless in most cases but occasionally congested (fig. 6). An increase in the number of endothelial cells of the capillaries of the tufts is occasionally seen. In several instances acute sclerotic changes, such as were described by Fahr³⁷ and Bell³⁸ have been observed in the afferent arteriole. Similar changes have been observed by us¹ and by others² in cases of pre-

eclampsia but not in pregnant women dying from causes other than toxemia.¹⁰

Liver lesions in cases of eclampsia are inconstant and were present in only 13 of 25 cases studied by us. Liver changes, as described by Fahr³⁷ and others, are characterized by capillary dilatation, hemorrhage, thromboses, stasis, hydropic and fatty degeneration and necrosis of hepatic cells and lymphocytic infiltration usually at the periphery of the lobule. Occasionally these changes are focal or are located in the midzone of the central portion of the lobule.

Infarcts are often present in the placenta. Microscopically, the placental lesions consist primarily of a premature aging process.¹¹ The normal full term placenta shows a certain amount of syncytial degeneration. Quantitatively this normal aging process involves

Fig. 6—Renal glomerulus in eclampsia. Note thickened basement membrane, aneurysmal narrowing of capillaries and degenerative tubular epithelium. Aniline blue stain. Reduced from a photomicrograph with a magnification of 600 diameters.

only 10 per cent to 50 per cent of the small villi at term. In toxemia however, the extent and severity of changes in the syncytium are greater. In severe cases, all the small villi may be involved. This difference is all the more significant because most of the toxemic placentas examined were delivered prematurely.

TREATMENT

The treatment of toxemia of pregnancy is prophylactic and therapeutic.

Prophylaxis—Perhaps the greatest strides in the control of toxemia have been in its prevention. Prophylactic treatment should consist in recognizing those

patients in whom toxemia is prone to occur, i. e. those with prepregnant hypertension, and in preventing if possible the development of generalized edema, which is the most frequent sign found by us to precede or accompany the onset of toxemia. Periodic examination of all pregnant women beginning as early in pregnancy as possible should include weight, blood pressure, urinalysis and examination for the presence of edema. All patients should be instructed to report at once the appearance of generalized edema or toxemic symptoms. With the appearance of edema, more than the usual supervision should be given even though in most cases it is by itself innocuous. The edema is preventable in many instances by maintaining adequate nutrition with a diet containing 100 Gm. or more of protein, a low value of salt, a high carbohydrate level and a caloric value of about 2,000. The diet should include lean meats and eggs with abundant fruits and vegetables. Fats, with the exception of a moderate amount of butter, should be eliminated. When patients adhere to a diet of low salt content there is no need to restrict fluid intake. Sodium bicarbonate and sodium containing preparations should not be used for heartburn. Preparations devoid of sodium such as magnesia magma or "amphojel" should be prescribed in the treatment of this symptom. In the more resistant cases diuretics are employed. Potassium chloride in 2 Gm. doses three to four times a day, ammonium chloride in 1 Gm. capsules six times a day for three days and repeated after an interval of three days⁴² or magnesium sulfate 8 Gm. daily by mouth may be beneficial in promoting loss of edema. Mercurial diuretics have met with little success in our hands. If the edema is pronounced and symptoms exist the patient should be put to bed for seven to ten days and placed on a 1,200 to 1,500 calory diet composed mainly of fruit juices, sugar and skim milk.

Treatment of Preeclampsia—The discovery of hypertension or albuminuria with or without edema in the first half of pregnancy indicates that vascular or renal disease exists independently of pregnancy (hypertension uninfluenced by pregnancy). Such patients should be watched with extreme care for the development of edema and toxemia. Preeclampsia is signaled by the appearance of a rise of blood pressure or an increase in albuminuria during the second half of pregnancy. When preeclampsia develops, we advocate that the patient should either be hospitalized or be put to bed at home and visited daily. Aside from bed rest and sedation for adverse symptoms, practically all effective therapy in preeclampsia (and eclampsia) consists in producing water elimination, whether by purges, restriction of salt and sodium bicarbonate in the diet, administration of diuretics or, finally, evacuation of the uterus. The dietary and fluid regimen and the administration of diuretics described in the preceding paragraph should be followed. If gastric disturbances exist a diet of fruit juices and skim milk suffices. Daily observations of weight, blood pressure, urine, edema and symptoms are essential for judging the progress of the disorder. Diuresis usually results from this regimen. Cerebral, visual and gastrointestinal symptoms can usually be controlled by sedation, preferably magnesium sulfate (10 cc. of a 25 per cent solution intramuscularly) or the barbiturates (e. g. sodium amytal 0.2 Gm. subcutaneously). If the condition of the patient becomes worse,

as evidenced by failure of diuresis or by maintained or rising blood pressure, albuminuria and other symptoms, evacuation of the uterus under the most favorable conditions offers the only consistently effective method of treatment. Before undertaking delivery all available general measures should be used in order to improve the bodily state of the patient. Accouchement force and cesarean section should be avoided as far as possible. We advocate rupture of the membranes or insertion of a Voorhes bag if the condition of the cervix warrants. Should the hypertension and albuminuria, even if slight, persist for a period of three weeks, we advocate considering termination of pregnancy as a safeguard against the development of permanent postpartum hypertension or albuminuria.

Treatment of Eclampsia—The appearance of coma or convulsions (eclampsia) or symptoms suggesting its approach are of considerable gravity to both mother and fetus. Therapeutic principles to be followed should consist in (1) general measures, (2) control of symptoms, (3) promotion of diuresis, (4) control of blood pressure and (5) possible evacuation of the uterus.

1 General Measures. These consist of bed rest in a warm, quiet, darkened room with constant observation. Recording of temperature and urine volume (by retention catheter) every two hours and recording of pulse, respiration and blood pressure every half hour should be maintained. Nothing should be given by mouth until the patient is conscious. Oxygen is indicated to combat cyanosis. A gentle soap-suds enema is given for elimination.

2 Control of Symptoms. For convulsions or for preconvulsive symptoms, heavy sedation is required. The three groups of sedatives most widely and successfully used are magnesium sulfate, barbiturates and chloral hydrate. The use of these sedatives as well as of morphine, veratrum viride and lumbar puncture has been described in detail.⁴³

3 Diuresis. Our observations have indicated clearly that the most reliable sign of improvement is diuresis, and until diuresis occurs improvement rarely takes place. For this reason an indwelling catheter with a two hourly recording of urinary output is serviceable. Pulmonary edema, cardiac decompensation, water intoxication, acidosis and other manifestations are secondary to the water retention and progressive renal shutdown. Should these complications develop, therapy should be directed toward their relief, but it is usually of little avail while oliguria or anuria persists. Venesection and plasmapheresis at this time increase rather than lessen the oliguria. Renal decapsulation is usually a harmful procedure. The administration of saline solution enhances edema formation and is contraindicated, as is also the administration of large amounts of parenteral fluids in the presence of edema.

Many factors enter into the excretory function of the kidney, two of the most important being maintenance of an adequate osmotic pressure of the blood and of an adequate blood pressure (see next paragraph). Diuresis may be aided and abetted by the slow administration intravenously of 50 cc. of 50 per cent dextrose. Transfusion or administration of concentrated protein solutions is the most important measure for promoting diuresis. It must be given slowly (500 cc. in two to three hours) with the patient in the orthopneic position in order to avoid pulmonary congestion.

4 Control of Blood Pressure. Although an extreme hypertension in eclampsia is of danger to the patient,

⁴² The administration of potassium and ammonium salts to patients with nitrogen retention is definitely contraindicated.

⁴³ Footnote deleted on proof.

⁴⁴ Footnote deleted on proof.

it has been our experience that the earliest sign of impending disaster is almost always an insidious, progressive fall in arterial blood pressure terminating in shock and death. This fall in blood pressure is often due in part to excessive use of sedatives, in part to indiscriminate blood letting and in part to the disintegration of the body as a result of the disease. Only too often are sedatives administered with the primary object of creating a hypotension rather than of controlling the convulsive seizure. This has already been emphasized. Venesection has been in vogue for several centuries. A rational consideration of its indications, however, reveals that it should be reserved for pulmonary edema alone. Maintenance of the blood pressure at normal or somewhat hypertensive levels is important. The blood pressure is more easily and reversibly controlled by the administration of magnesium sulfate or other sedatives given intravenously or intramuscularly than by venesection. Should the blood pressure fall to hypotensive levels, transfusion or administration of concentrated protein solutions is the most important measure for checking the progress of circulatory collapse. Although venesection may lower blood pressure, transfusion does not raise blood pressure above the normal level. If the process advances to the stage of outright shock with low blood pressure, pulmonary congestion, gasping respirations, cyanosis, coma, cold clammy extremities and the like, the prognosis is usually grave because irreversible changes have set in. Transfusion and cardiac and respiratory stimulants such as caffeine, nikethamide, digitals and hypertonic dextrose and sucrose may be of some help.

5. Evacuation of the Uterus. When all measures fail, evacuation of the uterus is invariably followed by relief, provided the process has not entered an irreversible stage. The astonishing disappearance of the symptoms and signs after delivery is truly dramatic. In the majority of cases of eclampsia there is improvement within twelve to eighteen hours of the institution of good medical therapy. An early effort should be made, however, to promote delivery. Unless the process has advanced to the stage of irreversibility, diuresis followed by other signs of improvement set in usually between twelve and twenty-four hours of delivery. The method by which pregnancy is terminated depends on many factors. If the cervix is "ripe," labor can usually be successfully induced by rupture of the membranes or insertion of a bag. Eclamptic patients are not good anesthetic or operative risks. We favor as the most satisfactory therapy the so-called middle course treatment which condemns routine accouchement force and cesarean section and which advocates improving the general condition and carrying the patient along until spontaneous delivery or delivery enhanced by dilation of the cervix is feasible.

COMMENT

Considerable mystery has surrounded the nature of the hypertensive toxemia of pregnancy.

It is a disease entity peculiar to the latter half of pregnancy with a clearcut pattern of characteristics which set it apart quite distinctly from other types of hypertension clinically and pathologically. Its closest analogue in the nonpregnant is acute glomerulonephritis, from which of course it differs etiologically and pathologically. Both represent however, an acute type of vascular disease characterized by hypertension, albuminuria and water retention. In each there is a diffuse involvement of the glomeruli of the kidney. Both may

leave irreparable renal damage and permanent vascular disease in their wake. Like acute glomerulonephritis, toxemia of pregnancy differs strikingly from the chronic forms of hypertensive vascular disease ("essential" hypertension, chronic glomerulonephritis, and so forth).

Post-toxemic hypertension and albuminuria are usually attributed to the persistence of a previously latent hypertension which has been made apparent by pregnancy. With this statement we are not in agreement. Evidence reviewed elsewhere⁴⁶ indicates to us that toxemia per se initiates the hypertensive process which becomes permanent after pregnancy. Clinically, this post-toxemic hypertension differs little if at all from the syndromes of benign or malignant nephrosclerosis of different etiologies. At autopsy, we have not detected any characteristic lesion in the kidneys of these patients. Indeed it is a common observation that the chronic effects of various types of initial renal lesions are identical or at least similar. The histologic lesion common to all is that of benign or malignant nephrosclerosis.

Many investigators have described animal syndromes which bear a superficial resemblance to human toxemia. On close examination, however, there are distinct differences.¹ Dill and his co-workers,⁴⁷ for example, have reported that experimental renal hypertension may be induced in pregnant rabbits and dogs with more ease than in nonpregnant animals and that delivery causes a distinct improvement in the hypertension. Their work has not been confirmed by Dawson, Cressman and Blacklock⁴⁸ in dogs. The syndrome produced in the rabbits resembled malignant hypertension with renal insufficiency rather than toxemia of pregnancy. Furthermore, when pregnancy occurs in animals hypertensive from renal ischemia, the blood pressure usually falls somewhat⁴⁹ as in human beings.⁵⁰ It would be fortunate if toxemia of pregnancy could be induced in animals, because it would open up a whole new field of investigation for the better understanding of the human disease.

Toxemia of pregnancy has been referred to as the "disease of theories," as indeed it is, which only indicates our lack of knowledge of its etiology. Space does not warrant more than a few brief etiologic observations here. More complete discussion will be found elsewhere.¹ It is apparent, however, that toxemia is not due primarily to uremia, liver insufficiency, hypoglycemia, electrolyte imbalance, hypocalcemia, guanidine intoxication, pyelonephritis, hypothyroidism, overactivity of the posterior pituitary gland or hypoproteinemia. Conclusive evidence is still lacking that a specific "toxin" is responsible for toxemia. Too little is known of hormone abnormalities in toxemia to evaluate the role they may play in its causation. From our own observations,¹ it appears that toxemia cannot be attributed to the fetus or to the uterine mass pressing

on adjacent structures such as ureter or renal artery. Evidence has been presented indicating the placenta as playing the primary role. The method by which the placenta produces this dyscrasia is not known.

SUMMARY

1 Results of a study of 100 normal pregnant patients, 100 pregnant patients with generalized edema and 80 patients with hypertension during pregnancy were correlated with and amplified by salient reports in the literature.

2 Approximately 75 per cent of all pregnant patients have easily demonstrable generalized edema which is only rarely of pathologic significance to the mother or fetus in the absence of hypertension and albuminuria. Its cause is unknown.

3 More than 90 per cent of previously normal patients have no vascular complications during pregnancy. Approximately 50 per cent of previously hypertensive or albuminuric patients suffer no aggravation of their hypertension or albuminuria during pregnancy regardless of the degree of hypertension or albuminuria before pregnancy. Since this lack of complications during pregnancy in hypertensive patients is not generally appreciated we have referred to it as "hypertension uninfluenced by pregnancy." Although the mother fares well there is a high incidence of miscarriages and stillbirths in this group.

4 Six to 9 per cent of previously normal patients have hypertension or albuminuria in the latter half of pregnancy, a syndrome known as toxemia (preeclampsia or eclampsia or convulsions occur eclampsia). Fifty per cent of our previously hypertensive patients had toxemia in the latter half of pregnancy. We were unable to predict which hypertensive patients would have toxemia on becoming pregnant.

5 Toxemia of pregnancy is an acute vascular disorder of the latter half of pregnancy which disappears before or soon after delivery. Clinically it resembles closely acute glomerulonephritis in respect to hypertension, albuminuria and generalized edema. Frequently there is development of permanent vascular disease subsequently.

6 The most important factors predisposing to the development of toxemia are generalized edema during pregnancy and prepregnant hypertensive vascular disease.

7 While the immediate maternal mortality in preeclampsia is almost negligible, in eclampsia it is high in the country at large.

8 There are no late effects of toxemia on the fetus. Permanent hypertensive cardiovascular renal disease of the mother occurs in approximately 25 per cent of patients with toxemia of pregnancy.

9 Post-toxemic hypertension and albuminuria are conditioned more by the duration of toxemia during pregnancy than by its severity. We advocate termination of pregnancy when toxemia, no matter how mild, has persisted for three weeks in spite of conservative therapy.

10 Post-toxemic hypertension differs in no essential details clinically or pathologically from other types of chronic hypertensive disease. At postmortem examination the characteristic lesions consist of nephrosclerosis.

11 Pathologically, the most characteristic and constant lesions in toxemia are in the kidney and consist of a glomerulonephrosis (Fahn). Liver lesions are inconstant but when present consist typically of lesions in the periphery of the lobule. Placental lesions are

characterized by infarction and premature syncytial degeneration.

12 There is danger in venesection and excessive sedation. Interruption of pregnancy after three weeks of conservative therapy to prevent the occurrence of permanent vascular disease in the mother is advocated.

13 The etiology of toxemia of pregnancy is unknown, although evidence points to the placenta as being primarily responsible for the condition.

CONTINUOUS CAUDAL ANESTHESIA OR ANALGESIA

A CONSIDERATION OF THE TECHNIC, VARIOUS RISKS AND SOME POSSIBLE DANGERS

R. CHARLES ADAMS, M.D.

JOHN S. LUNDY, M.D.

AND

THOMAS H. SELDON, M.D.

ROCHESTER, MINN.

In the many recent advances in the rapidly expanding field of anesthesiology another new method has been added namely continuous caudal anesthesia or analgesia. The method was introduced as a new means of producing obstetric anesthesia and analgesia but it also has possibilities as a method of anesthesia for certain surgical operations.

Throughout the ages, physicians have been attempting to arrive at a method of anesthesia which would render labor and delivery painless without increasing the hazard to either mother or child. Few, if any, of the methods heretofore developed have even remotely satisfied these three demands. There are certain indications which lead many physicians to believe that continuous caudal anesthesia will meet these demands in most cases. It is only natural that the apparent answer to such an important problem should create intense interest among both the medical profession and the public.¹ Many successful results have been reported up to this time and the use of the method is increasing rapidly.

Although we are convinced that the principles of this new method are sound and that its use will continue to expand we wish to point out to those who contemplate using the method that the technic may be difficult and that it may be accompanied by certain potential dangers and complications. If continuous caudal anesthesia is to be employed with safety, the anesthetist must be both adept in the technic of the method and fully aware of all the potentialities involved. In this paper we wish to emphasize the technic of the method together with its potential hazards as well as its desirable features.

DEVELOPMENT OF THE METHOD

Continuous caudal anesthesia has been founded on a number of earlier methods, among which are caudal block,² transsacral block,³ high caudal block,⁴ peridural block and combinations of these methods.

From the Section on Anesthesia, Mayo Clinic. Because of lack of space, this article is abbreviated here. The complete article appears in the authors' reprints.

Continuous caudal anesthesia was originated and developed by Edwards and Hingson⁶ and the preliminary report of their results appeared in September 1942. Its preliminary trial in October 1941 involved its use for several surgical procedures on the perineum and lower extremities. Its first obstetric application was carried out by Hingson and Edwards on Jan 6, 1942. Up to the present they have used the method and studied the results in 600 cases. In their earlier cases Hingson and Edwards employed a type of equipment similar to that which Lemmon⁷ used for continuous spinal anesthesia, namely a malleable needle of the Lemmon type to which was attached an extension tubing to permit the administration of additional doses of the local anesthetic solution throughout the course of labor and delivery. Subsequently they modified the equipment somewhat (fig 1).

After a preliminary trial of the method of Hingson and Edwards we devised an alternative technic (fig 2). This involved the use of a ureteral catheter inserted into the caudal canal through a large caliber needle and through which the local anesthetic solution was injected. This apparatus was developed with the idea of preventing possible breakage of and trauma from a semirigid needle in the caudal canal and to help permit greater freedom of movement of the obstetric patient during the course of her labor without the hazards of trauma or breakage of the needle.

After instituting this technic and using it in a number of cases we learned that Manalan of Indianapolis had employed a ureteral catheter in a number of cases to produce anesthesia and analgesia for obstetric delivery, although not as a continuous method for the relief of pain during the course of labor.⁸ Thus as often happens in medical development, two similar technics

1940 to Nov 15 1941. The preliminary report of his work appeared in October 1942.

We have used and are continuing to use the method of Hingson and Edwards and the one developed by us in both obstetric and surgical cases. Both methods have certain advantages and certain disadvantages according

were evolved independently by Manalan and ourselves. Manalan⁹ employed this method of anesthesia and analgesia in obstetric delivery in 46 cases from Aug 13,

to our present concepts. Throughout the following pages the technic of both methods will be described. Neither of these methods should be attempted by physicians who are not experienced in the use of caudal-sacral block anesthesia. It is suggested that those who contemplate the use of the method should first familiarize themselves with the technical features of the method in general. Tuohy¹⁰ has applied the catheter technic to continuous spinal anesthesia in a limited number of cases and feels that this method may be applicable in certain cases in which continuous spinal anesthesia is indicated.

Technic—The needle is inserted into the midline of the caudal canal through the sacral hiatus which is covered by the sacrococcygeal ligament. Its point is advanced to the level of the third sacral foramen and never higher than the level of the second sacral foramen, owing to the possibility of puncturing the dural sheath.

Anesthetic Agents—Various local anesthetic agents have been employed but a 1.5 per cent solution of metvame has been preferred by most authors. Isotonic solution of sodium chloride is used as the solvent and the amount of the solution required will depend on the desired concentration of the anesthetic agent and whether or not it is supplied in a concentrated solution or in a solid form. The accompanying table shows the method of diluting the contents of a 5 cc ampule of a 20 per cent solution of metvame in order to prepare weaker solutions of this drug.

THE METHOD OF HINGSON AND EDWARDS

The special apparatus devised by Hingson and Edwards, which has been described is depicted in figure 1. The needle was specially designed for this technique. It is made of stainless steel, it is semiflexible and malleable, it is of 19 gage and is $3\frac{1}{2}$ inches long.

Preparation of Different Solutions of Metycaine by Adding Isotonic Solution of Sodium Chloride to the Contents of a 2 cc Ampule of a 20 per Cent Solution of the Drug

Strength of Final Solution, per Cent	Isotonic Solution of Sodium Chloride, cc and
0.5	200 cc
1.0	100 cc
1.5	75 cc
2.0	66.6 cc
	50 cc

The needle is inserted while the patient is in the knee-chest or the lateral flexed position. It is inserted into the caudal canal a distance of 1 to 2 inches.

In the series of cases reported by Hingson and Edwards¹¹ the average duration of anesthesia was six and a half hours and the average total dose of metycaine was 2.6 Gm. According to these authors there was no alarming fall in blood pressure or any toxic reaction and the babies were born in vigorous condition. Nausea occasionally occurs but even patients who are nauseated may take fluids and food during the course of labor. In most instances this method produces complete relief of pain during both delivery and labor and is satisfactory for such operative procedures as episiotomy and perineal repair.

AN ALTERNATIVE METHOD

An alternative method of continuous caudal anesthesia entails the use of a metered catheter. This method was first employed in June 1942 and was evolved in order to eliminate the danger of breakage of needles and the possibility of trauma during labor. It is applicable for both obstetric and surgical procedures. In addition it was felt that the use of flexible equipment might permit greater freedom of movement on the part of the patient, particularly during the course of a long labor.

Preliminary Medication—Premedication with a barbiturate such as pentobarbital sodium is employed particularly to guard against untoward effects of the local anesthetic. This drug is administered orally in comparatively small doses, that is, $1\frac{1}{2}$ to 3 grams (0.1 to 0.2 Gm). It may or may not help to relieve the preliminary pains of labor.

Equipment and Solutions—The same equipment and solutions may be used for obstetric or surgical procedures.

Equipment A sterile "continuous caudal tray" (fig 3) should be prepared. This tray should contain

- One number 5 ureteral catheter
- One 13 gage Love-Barker intraspinal needle with stylet
- One 20 cc Luer-Lok syringe or a 10 cc Lundy syringe with Lundy-Luer adapter
- One Lundy 50 mm needle
- One Lundy wheel needle
- One Luer wheel needle

- One 18 or 20 gage Luer intravenous needle $1\frac{1}{2}$ inches long
- One 22 gage Luer hypodermic needle
- One Luer needle plug
- One Luer adapter
- One 200 cc graduated cup

Solutions The following ampules of solution are sterilized and placed on the "continuous caudal tray"

- Two 5 cc ampules of a 20 per cent solution of metycaine
- Two 1 cc ampules of 1:2,600 solution of epinephrine
- Isotonic solution of sodium chloride

We have also used a 1.5 per cent solution of procaine hydrochloride, but we prefer a 1.5 per cent solution of metycaine because the duration of the resulting anesthesia is greater than the duration of anesthesia produced with procaine hydrochloride. Unless the patient's blood pressure is abnormally high, 1 cc of a 1:2,600 solution of epinephrine is added to 66.6 cc of the 1.5 per cent solution of metycaine. This increases the duration of anesthesia and permits the use of smaller total doses of metycaine.

Administration—The following description of the administration of an anesthetic to produce continuous

Fig 3—Sterile continuous caudal tray. The Lundy syringe, needles and Lundy Luer adapter may be omitted from this tray and only the Luer syringe and needles may be used for the preliminary infiltration but the use of the Lundy Luer syringe facilitates the accomplishment of the first part of the injection.

caudal anesthesia will pertain chiefly to the use of this method of anesthesia in obstetric practice.

For primiparas the administration of the anesthetic solution is begun when the diameter of the dilating cervix has reached 2 to 3 cm and when the labor pains have become severe. For multiparas and when labor is advancing rapidly the solution is injected somewhat earlier. For these patients the injection may be administered while they are on the delivery table, but when labor is more protracted the solution may be injected in the patient's room or in the predelivery room. The type of anesthesia and its effects should be explained to the patient before the administration of the anesthetic agent is begun.

The patient is placed in the knee-chest position or in the modified Sims position. When the modified Sims position is used, most physicians place the patient on her left side, however, Mousel¹² has expressed the opinion that the insertion of the needle and catheter can be facilitated by placing the patient on her right side. The anesthetist should face the patient. The patient is

11 Hingson, R. A., and Edwards, W. B. Continuous Caudal Anesthesia During Labor and Delivery, *Anesth & Analg* 21: 301-311 (Nov-Dec) 1942.

12 Mousel, L. H. Personal communication to the authors.

moved close to the edge of the bed or delivery table. When this method of anesthesia is used for surgical operations the patient is placed in the prone position and her hips are elevated with pillows or a sacral rest.

The sacral region is sterilized widely about the proposed site of injection and the patient is draped. A skin

The needle should be introduced slowly and cautiously, and it is desirable that the bevel of the needle does not scrape the bone of either the anterior or the posterior wall of the canal, since this can result in trauma to the venous plexus lining the canal. The point of the needle is advanced to about the level of the third sacral foramen but never as high as the level of the second foramen. In many instances it is necessary to insert the needle only 1 to 1½ inches into the caudal canal.

After the needle has been inserted to the correct position, the stylet is removed and a number 5 ureteral catheter (woven silk or, preferably, nylon) is passed through the needle and into the caudal canal. It is advanced so that as determined by previous measurement its tip will rest at about the level of the third sacral foramen or between the second or third foramen (fig 5). If the ureteral catheter is of the graduated type its position at the proper level of the caudal canal may be determined more accurately.

The catheter is then grasped distal to the needle to maintain it in the proper position while the 13 gage needle is withdrawn over it by combined pull and rotation. The catheter is left in place in the caudal

Fig 4—The 13 gage needle has been inserted into the caudal canal up to the level of the third sacral foramen. The stylet has been partially withdrawn.

wheel is raised over the middle portion of the sacral hiatus. A 20 gage intravenous needle 1½ inches long is attached to the syringe containing the anesthetic solution and is inserted through the skin wheel and through the sacrococcygeal ligament at an angle of 45 degrees. After the needle has pierced the sacrococcygeal ligament and has come to rest lightly on the anterior wall of the sacrum 5 cc of the solution of metcaine is injected. Even this preliminary injection into the lower part of the caudal canal sometimes will produce partial analgesia.

This needle is withdrawn and a 13 gage Love-Barker needle^{12a} with its stylet in place and with the bevel directed upward, is inserted at an angle of about 45

Fig 5—The stylet has been withdrawn from the 13 gage needle and the catheter has been introduced through it into the caudal canal.

degrees (fig 4) and introduced through the sacrococcygeal ligament. When this needle touches the anterior wall of the sacral canal its bevel is turned downward and its hub depressed after which it may be cautiously advanced upward along the midline of the caudal canal.

Fig 6—After the catheter has been inserted to the proper level in the caudal canal the 13 gage needle is withdrawn over the catheter.

canal (fig 6). The patency of the catheter should be checked before it is inserted. After the 13 gage needle has been withdrawn, 5 cc of the local anesthetic solution is injected through the catheter into the caudal canal to check the patency of the lumen of the catheter and also to test for any possible untoward reaction to a small dose before larger doses are injected (fig 7).

It is important during these maneuvers that the external end of the catheter be kept sterile. When the catheter is in place in the caudal canal a 22 gage Luer hypodermic needle the bevel of which has been cut off square is inserted into the catheter end and is held there with a small piece of adhesive tape. A sterile Luer cap is then applied to the hub of this needle, this will block any backflow of solution and will keep the end of the needle sterile.

Before the adhesive tape is applied, the skin about the site of the catheter is painted with a solution of mastic of benzene and a small sterile piece of sponge rubber or rubber dam is slipped over the catheter and is pressed firmly against the skin which has been painted with the adhesive preparation. This forms a tight seal around the catheter and its point of exit and helps to prevent soiling and contamination by any secretions.

12a Love LC: Continuous Subarachnoid Drainage for Meningitis by Means of a Ureteral Catheter. *J A M A* 104:1595-1597 (May 4) 1935.

Several pieces of waterproof adhesive strapping are applied to the catheter at its exit from the skin both to hold it in position and to form a seal around the exit of the catheter to prevent contamination from vaginal or rectal soiling. The remaining portion of the catheter is curved laterally and strapped to the skin of

Fig. 7—Preliminary injection of 1.5 per cent solution of metyrcaine through the catheter into the caudal canal prior to the fixation of the catheter with adhesive tape.

the flank by adhesive tape the end of the catheter being left in an accessible position for repeated injections (fig. 8).

Thirty cc of the anesthetic solution is injected very slowly, about 10 cc at a time. This slow injection is important, since a large volume of solution injected rapidly at one time may cause pain, nausea, headache and other untoward effects which result from excessive pressure within the caudal canal or from rapid absorption of the anesthetic agent. Such reactions are an indication that the anesthetic solution has entered the caudal canal. If the anesthetic solution is warm when it is injected its effectiveness will be increased, that is, the period of induction will be shortened and the degree of anesthesia will be increased.

After the injection has been made the patient may be turned on her back and during the course of her labor she may lie in any position in which she is comfortable. She may change her position at any time without assistance, provided the catheter has been securely fixed at its point of exit from the skin. There is little danger of dislodging it and there is no danger from trauma.

Additional injections of 10 cc, but not more than 20 cc, of the solution of metyrcaine are administered at the first signs of reappearance of the labor pains. Once the catheter has been inserted and anesthesia obtained, the subsequent anesthesia parallels that obtained by the needle technic. The catheter is removed after the delivery or other operative procedures have been completed and before the patient is returned to her room. The site of puncture is painted with an anesthetic solution, and a small sterile dressing is applied.

POSSIBLE COMPLICATIONS AND PRECAUTIONS

Those Associated with the Needle Technic—The possible complications to caudal block¹³ in general have been frequently emphasized, and these apply equally to continuous caudal anesthesia. Most of the dangers and untoward effects occur at the time of the injection

Variations in the bony formation of the sacrum, obese patients in whom the bony landmarks are difficult to palpate, previous injuries and deformities in the sacral region and faulty position of the patient at the time of injection serve to increase the difficulties and the possibility of untoward effects or inadequate anesthesia.

Faulty Position of the Needle A common error, which occurs particularly when the patients are obese, is to miss the sacral hiatus and insert the needle over the posterior wall of the sacrum. It thus comes to lie underneath the skin overlying the sacrum, and no anesthesia will be obtained since the anesthetic solution will be deposited subcutaneously.

Intravenous Injection It is possible, by scraping the point of the needle along the anterior or posterior bony wall of the caudal canal, to pierce the venous plexus within the canal. Unless this is determined by aspiration before injection and the point of the needle is adjusted, it is possible to inject a toxic dose of the local anesthetic agent into the venous system. This will produce untoward and perhaps fatal reactions.

Subarachnoid Injection If the point of the needle is kept below the level of the second sacral foramen it is not likely that the needle will pierce the subarachnoid space. It is advisable to insert the needle to a point well below this level. Frequent aspirations should be carried out to see if spinal fluid can be withdrawn, before any local anesthetic solution is injected. Severe collapse and possibly death can occur if an overdose of a local anesthetic agent is administered intraspinally in this manner.

Broken Needles Breaking of a needle has occurred more frequently during the early phase of the development of the method than it has in recent months. Hingson and Edwards have experienced little difficulty since the development of their new needle, which is supported at the hub. They did, however, instruct their patients to maintain a lateral position during the course of the anesthesia and to turn in bed with caution in order to prevent undue pressure on the needle. We feel that this

Fig. 8—The exit of the catheter from the skin is thoroughly fixed with waterproof adhesive tape both to hold it in place and to prevent contamination of the point of exit by soiling. The catheter is carried across laterally and fixed to the skin over part of its length by adhesive strapping. A 20 gauge Luer needle has been inserted into the distal end of the catheter and fixed in place by a small piece of adhesive tape. Between injections the hub of this needle is protected and kept sterile by a Luer cap. The end of the catheter is carried around to the flank so that it rests in accessible position for repeated injections.

is a wise precaution when any type of needle is employed in this technic for the following reasons:

1. Since the point of the needle may impinge on bone within the caudal canal, any pressure on the hub of the

¹³ Adams, R. C., and Tuohy, E. B. Sacral Block Anesthesia. A Consideration of the Unusual Difficulties Encountered and a Report of Two Unusual Cases, *Minnesota Med.* 21: 397-402 (June) 1938.

needle will predispose to bending of the needle or to trauma inside the canal, if not in actual breakage of the needle

2 If, by the patient's movements, the hub of the needle is made to move from side to side, it seems reasonable that the sacrococcygeal ligament will act as a fulcrum and that a corresponding movement will be set up in that portion of the needle within the caudal canal. It will appear that under certain circumstances this could produce trauma to the nerves and vessels

3 Breakage of a needle in the caudal canal may necessitate incision for removal and in some cases has necessitated laminectomy. These are serious procedures in an obstetric case and demonstrate the necessity of both technical skill and careful institutional supervision. One of the chief methods of prophylaxis against breakage of needles during continuous caudal anesthesia is the use of one needle in only 4 or 5 cases. Should there be any doubt as to the needle being defective or weak, another needle should be substituted. If breakage of a needle within the caudal canal should occur, it should be removed with the least possible delay in order to prevent the increasing danger of irritation and infection. It is wise to remove it within twenty-four hours.

Unilateral Anesthesia This has occurred in a few cases, presumably owing to lateral deviation of the point of the needle. This can usually be corrected by adjustment of the needle so that the anesthetic solution reaches the nerve trunks of the unanesthetized side.

Those Associated with the Catheter Technique—Although the use of the catheter obviates the danger of breakage of the needle and of trauma, other possible complications peculiar to its use must be borne in mind.

Trauma The 13 gage needle through which the catheter is introduced is large and can produce trauma if two or more attempts are made to insert it. If only one insertion is necessary, the trauma can be kept minimal as the needle need not be inserted into the caudal canal for a distance of more than 1 or 2 inches and it remains in the canal only for a matter of seconds or minutes.

If more than one puncture is required, trauma may occur. This will increase the possibility of irritation and infection. If a second puncture in a different location has been made, leakage of the local anesthetic solution through the original site of puncture has occurred. This lessens the chances of complete anesthesia and increases the possibility of infection. On this basis we do not feel that multiple punctures should be made if the first one is unsuccessful.

Care of Catheters Catheters should be carefully examined for defects before use and old or cracked ones discarded. Catheters are sterilized by boiling in an antiseptic solution. When not being used, they are stored in a container which prevents kinking or buckling.

Intradural Injection Although the danger of puncturing the dura with the catheter is remote, incomplete anesthesia may result from inserting the catheter too high in the caudal canal. This causes the solution to be deposited at too high a level and thus it may not get in contact with all the sacral nerves. However, even if the danger of inserting the tip of the catheter through the dura is remote, there is nothing to prevent the catheter entering the dura when the 13 gage needle is inserted to too high a level in the caudal canal. It is both unnecessary and unsafe to insert this needle higher than the level of the third sacral foramen.

Curling of the Catheter The catheter may become curled within the caudal canal and its tip may thus be deflected to one side or the other or backward toward the hiatus. This also may result in incorrect distribution of the anesthetic solution and lead to incomplete or unilateral anesthesia.

Fearing the Catheter If the catheter has been advanced too far into the caudal canal and it becomes necessary to withdraw it to the proper level, the 13 gage needle should be withdrawn as well and both the needle and the catheter reinserted. If an attempt is made to withdraw the catheter without withdrawing the needle, the catheter may become caught on the sharp bevel of the needle. Traction on the catheter under such circumstances may result in shearing off its tip in the caudal canal.

Manipulation of the Catheter The catheter may be so slender that it may be difficult to manipulate properly.

MISCELLANEOUS EFFECTS COMMON TO THE TWO METHODS

Very rapid injection of the anesthetic solution or the injection of a large amount of solution at any one time may produce headache, dizziness, a feeling of pressure in the legs or over the sacrum and momentary syncope-like effects. Some patients experience headache of varying duration during the postpartum period. This might be attributed to the anesthetic in some cases. In some cases the blood pressure drops during the period of anesthesia, but this reaction seldom has been acute or alarming. Gready and Hesseltine¹⁴ reported a case in which the method was employed for an anticipated abdominal cesarean section in a case of toxemia and hypertension. The systolic blood pressure, which had been 190 mm of mercury, fell to an indeterminate level. The patient recovered after the administration of oxygen by inhalation and of ephedrine hypodermically, but no operation was performed at the time.

Certain contraindications have been noted. Such conditions as placenta previa, inertia uteri, hysterical or psychotic states and disproportion between size of the child and pelvis are definite contraindications to the use of the method. It therefore is obvious that the nature of the case should be thoroughly understood before the choice of the anesthetic is made. Gready and Hesseltine said that the method is contraindicated for difficult rotation and versions, since complete uterine relaxation is desirable for these procedures. Other contraindications include a history of hypersensitivity to local anesthetic agents, infective processes over the sacrum and sacral hiatus, and congenital or traumatic malpositions of the vertebral column, especially of the sacral segment.

Hingson and Edwards¹⁵ expressed the opinion that a solution of epinephrine should be withheld from the local anesthetic solution as it might predispose to uterine inertia. It is our feeling that this possible undesirable effect may be outweighed by the increased duration of anesthetic effect produced by its use in suitable cases. We have not found the use of epinephrine to be disadvantageous. It is omitted, however, from the local anesthetic solution if the patient has any type of hypertension or if there is a history of idiosyncrasy to the drug. There is possibly less fall in blood pressure as a result of the caudal anesthesia in cases in which epinephrine is employed. If there is no contraindication to the use

14. Gready, T. G. Jr. and Hesseltine, H. C. Continuous Caudal Anesthesia in Obstetrics. *J. A. M. A.* 121: 229-230 (Jan. 23) 1933.
15. Hingson, K. A. and Edwards, W. B. Continuous Caudal Anesthesia in Obstetrics. *J. A. M. A.* 121: 227-229 (Jan. 23) 1933.

of epinephrine we employ it in the following amounts. One cc. of a 1:2600 solution or 6 minims (0.1 cc.) of a 1:1000 solution is added to 66.6 cc. of a 1.5 per cent solution of metycaine. If total doses larger than 66.6 cc. of the 1.5 per cent solution of metycaine are required the epinephrine may be omitted from the subsequent doses, particularly if the patient's blood pressure becomes elevated above normal.

One advantageous feature of this method of anesthesia is that if complete anesthesia is not obtained there does not appear to be any contraindication to the supplementary use of suitable anesthetic agents by inhalation.

If the cardiovascular system is normal or nearly normal, injection may be administered while the patient is in the knee-chest or the modified Sims position, but if a cardiovascular lesion such as severe cardiac decompensation is present the knee-chest or the knee-elbow position should not be used. If orthopnea is present, the patient cannot be placed in this position with safety and the modified Sims position will be indicated.

COMMENT

We have used both of these methods of continuous caudal anesthesia. Our results will be published subsequently in addition to the results obtained in a series of cases in which operations were performed on the anus and lower part of the rectum, perineum, vagina, uterus, urogenital tract and adjacent parts. The method is still comparatively new and there is much to learn concerning further details and safeguards related to its technique.

We are of the opinion that for the present, at least, its use should be confined to institutional practice and in obstetric clinics where its administration will be accomplished and supervised by physicians experienced in the various techniques of caudal anesthesia and its possible indications and contraindications. This precautionary attitude concerning the use of the method generally has been stressed by Hingson and Edwards and others. A recent editorial¹⁶ in *THE JOURNAL* contained the following statement: "The technique is one which demands the competent art of the specially trained anesthetist or surgeon and the practice of a high order of obstetric science. It is not a method for indiscriminate use in the home or by those who have not been especially trained in its technique or in a realization of conditions which might contraindicate its use."

The method, in general, is undoubtedly a decided step forward in obstetric anesthesia and analgesia. The pioneer work of Hingson and Edwards has laid the foundation for those who will use the method in future years, and these investigators are to be complimented on their well controlled experimental and clinical researches. Except for earlier difficulties associated with technical phases of the injection, which have been noted by all who have employed the method, it would appear to produce satisfactory results for both the mother and the baby.

SUMMARY

Two methods of continuous caudal anesthesia appear to have certain advantages and certain drawbacks. Certain technical difficulties associated with the early clinical trial of both methods are being avoided by improved equipment and increased experience in the application of the methods. There are certain dangers and precautions which apply to both single dose and continuous caudal anesthesia. Both methods have certain advantages

and disadvantages. The disadvantages include complications due to breakage of needles, intravenous injection, trauma, subdural injection and infection. Certain suggestions have been made concerning the technique of both methods in order to obviate these untoward occurrences. Fundamentally, the method produces excellent anesthesia and analgesia for both labor and delivery and should carry a wide margin of safety for mother and child. Careful anesthetic records of the technique and course of anesthesia should be kept. Since most of the dangers, drawbacks and untoward effects have been associated with certain technical difficulties which could not be foreseen in the early phases of the work by even experienced physicians, it is suggested that for the present, at least, the use of the method be confined to institutional practice by persons trained and experienced in caudal anesthesia.

AN OUTBREAK OF HALOWAX ACNE ("CABLE RASH") AMONG ELECTRICIANS

LOUIS SCHWARTZ, M.D.

Medical Director, United States Public Health Service
BETHESDA, MD

The first observations on the development of acne-like lesions among workers in the United States coming in contact with chlornaphthalenes and chlordiphenyls as well as acute yellow atrophy of the liver occurring among such workers were reported¹ in 1935. Since that time many authors have reported similar observations.

Despite the fact that these compounds, if used without proper safety precautions, cause a high incidence of skin conditions and, in certain processes such as coating wires, also entail the serious hazard of acute yellow atrophy of the liver, they are still being used as dielectrics and insulators, because they are waterproof and have excellent heat resisting and flame proof properties.

Since our entrance into the war, the speed-up in our shipyards has in many instances resulted in failure to install the proper safety precautions necessary when handling wires insulated with these substances.

Reports have been received by the U. S. Public Health Service from several shipyards of acne-like lesions occurring among electricians installing heat and flame proof cables in ships. Investigations have always shown that the cables causing the trouble were coated with chlornaphthalenes and chlordiphenyls (halowax). The most recent investigation was made in response to a request from the health officer of one of our Western states for an investigation of an outbreak of dermatitis among electricians working in the shipyards of that state. The electricians had become alarmed because some among them had developed acne-like lesions; they had read in the newspapers of three workers who had died of acute yellow atrophy of the liver at the plant where the wires with which they worked were made. It was only with great difficulty that these electricians were persuaded to remain at their work until the arrival of the representative of the U. S. Public Health Service to make an investigation.

Immediately on his arrival, a conference was arranged to bring together representatives of the workers' unions,

representatives of the state health department and superintendents of the shipyards. At the meeting it was decided to visit all shipyards where the so-called "cable rash" was reported and to examine the workers suspected of having "cable rash" in order to ascertain whether all the cases of dermatitis were caused by handling cables.

In the first shipyard visited it was found that dermatitis was limited to cable "strippers." The work was performed in the intercommunication room of the ship. In plant A, 8 persons were presented for examination as suffering with "cable rash." Seven of these were found to have halowax acne. In plant B, 22 cases, all halowax acne, were presented, all of these occurred in electricians engaged in "stripping" cable. In this shipyard, electricians affected worked for several months on "stripping" cable in the intercommunication room. They stated that about two months had elapsed before they noticed signs of the acne on the face. Those who had worked longest were most severely affected. None of the workers showed signs of systemic poisoning. Samples of the wire which the workers "stripped" were examined. It was noted that one of the cables made by the company where deaths had been reported contained considerable amounts of halowax impregnated into asbestos and wrapped around the wire as insulation. The halowax was loosely contained in the asbestos and flaked off easily as the wires were being "stripped."

In the second shipyard visited it was found that the "strippers" worked only part time at "stripping" and at other electrical work the rest of the day. It was also found that the type of cable described was not being used. There was being used, however, another type of cable made by the same company from which the halowax did not flake off so readily. Twenty-one electricians who had been engaged at various times in "stripping" were presented for examination. While various skin conditions were noted, such as insect bites, impetigo and pruritis hiemalis, there were no cases of halowax acne.

In the third shipyard visited it was again found that cable being "stripped" was not the type from which the halowax flaked easily and the electricians worked only part time at "stripping." Nineteen cases of so-called cable rash were presented for examination but none of them proved to be halowax acne. They were the various skin diseases such as those found among workers in the second shipyard inspected.

In the fourth shipyard visited the operation performed by the electricians was the same as observed in the other yards. Among 12 cases of so-called cable rash presented for examination there were no cases of halowax acne.

Samples of cables from all four yards were compared. It was found that the cable most used at the first shipyard and to which the workers attributed the "cable rash" was so coated with halowax that in the "stripping" operation the halowax flaked off easily and scattered on the hands and clothes of the "strippers." Moreover, at this shipyard more halowax coated cable made by the company where the deaths had been reported was used than at any of the other yards. Workers at this shipyard had been engaged in "stripping" for a longer time than in the other shipyards and "stripped" all day instead of only part of the day as in the other shipyards. Cables made by other companies were found to have halowax insulation, but the halowax

was more tightly held against the wire and more firmly impregnated into the asbestos so that it did not flake easily.

From this investigation it seemed evident that the constant handling of cable in which halowax is loosely packed and flakes off is responsible for the acne occurring among the "strippers" in the first shipyard inspected.

When this conclusion was reached, a meeting with the dermatologists of the city was held and cases of halowax acne were presented. This was done with the purpose of acquainting physicians with the disease and outlining for them approved methods of treatment.

The diagnosis of halowax acne was determined by (1) the history of industrial exposure to halowax, (2) the appearance of the lesions and (3) their location. The history will show that the worker was engaged in

Fig. 1—Halowax acne on an electrician. Note cysts behind ears and on ear cartilages.

an occupation in which he came in contact with halowax or its fumes for a period of a month or more before the lesions began to appear. In this case the occupation was "stripper" of wires on heat and flame proof cables insulated with halowax. Lesions are pinhead to pea size pale straw colored cysts formed by plugging of the orifices of the sebaceous glands, resulting in retention of the secretion and in the keratinization of the lining membrane. Cysts are located on the face, lobes of the ears, retroaural folds back of the neck, shoulders, abdomen around the navel, thighs and wherever the halowax soiled clothes may touch the skin. It is not unusual to see similar lesions in the wife and children of the worker caused by contact with the soiled work clothes if they are worn or washed at home.

Once seen, halowax acne (fig. 1) cannot be mistaken for anything else except perhaps coal tar pitch acne, from which it can be differentiated by the history of the occu-

pational exposure. Acnes caused by chlorodiphenyl chloronaphthalenes and chlorodiphenyl oxide are identical in appearance with halowax acne. It is possible for the immature to confuse acne vulgaris with halowax acne especially if the halowax acne occurs in a patient of acne age.

The differential points other than age and occupational exposure are given in table 1.

The microscopic examination of a typical halowax cyst (fig. 2) made by Surgeon Samuel M. Peck (R) is as follows:

The epidermis shows relatively little except for some scaling without parakeratosis. We see the evident widening of the follicular openings and the formation of hyperkeratotic plugs. Here we see horned cysts down in the cutis and in the deeper portions of hair follicles both in and around it there is a

Fig. 2—Biopsy section of chloracne from chloronaphthalenes and chlorodiphenyls (reduced from photomicrograph originally published in Public Health Reports.)

marked inflammatory reaction. An almost tuberculoid granulation tissue is seen consisting of dense accumulations of both foreign body and Langerhans type of giant cells. Between these giant cells are many histiocytes and lymphocytes, the histiocytes in many instances having the characteristics of epithelioid cells. In the serial sections it can be seen that these horned cysts situated in the middle cutis are extensions of the enlarged hyperkeratotic follicles in which the whole follicular apparatus has been replaced by a huge invaginated structure full of horny material which has pressed against the rest of the structure causing atrophy with the resultant formation of horned cysts. Also from the serial sections it is evident that the dense mass of foreign body granulation tissue reaction is situated in and around remnants of sebaceous glands and hair bulbs.

Interpretation—The process is analogous to acne in that we have plugging of the follicular openings, follicular and perifollicular inflammatory reactions and a foreign body giant

reaction which is often associated in acne with the escape of sebaceous gland contents into the surrounding tissues. It differs from acne in that the plugging of the follicular openings is due almost exclusively to a hyperkeratotic process which seems to include not only the mouth of the hair follicles, but also extends downward, following the invagination into the

TABLE 1—Differential Points

Halowax Acne	Acne Vulgaris
Usually occurs on face, behind ears, on neck, chest, abdomen	Usually occurs on face, back and chest
Comedones, while present, are not a prominent feature	Comedones are a predominant feature
Vesicle lesions are usually pale, straw-colored, noninflammatory cysts	Lesions are inflammatory
Contents of cysts consist mostly of keratin plus sebaceous matter	Contents of lesions consist of sebaceous matter and inflammatory exudate
The skin may be dry	The skin is greasy
The lesions are persistent	Individual lesions are transient

associated structures. In acne we ordinarily have a combination of follicular hyperkeratosis and excessive secretion of the sebaceous glands. The last seems to play a very little role in this process. There is no real comedo present, but more like the follicular hyperkeratosis seen in ordinary vitamin A deficiencies.

Of most importance in the treatment of these cases is the treatment of the skin with tincture of green soap or a synthetic wetting agent. The synthetic wetting agent is to be preferred and should consist of 10 per cent aqueous solution of either Igepon, Duponol, Santomene, Naccanol or Aerosol. It is not advisable to add a sulfonated fatty oil to the wetting agent because the sulfonated fatty oils decrease, if anything, the defatting powers of such a solution of wetting agent as is given.

Comedones should be expressed and cysts evacuated two or three times each week. The comedones may be expressed by the nurse in the plant, but a physician should perform all operations which require incision of the skin in order to evacuate cysts. A mild peeling solution such as lotio alba is advised for use at night. If x-rays are used, they should be administered with great

caution especially if the patient is beyond the acne age, as in these patients the skin is usually dry and further depression of the function of the sebaceous glands is not desirable.

At the final meeting of the representatives of the health department, the workers and superintendents of the shipyards the following recommendations were made:

Since no cases of halowax acne were found in three of the yards, there need not be any special precautions taken by the electricians in these yards as long as they handle the same kind of cables as they have been handling and as long as they do not spend most of their time in "stripping", however, if at any time they must handle the special cable with the loose halowax insulation, they should also take these precautions

1 It is recommended that workers engaged in "stripping" cable containing either chlornaphthalene, chlordiphenyl or chlordiphenyl oxide be supplied with hood respirators. It is preferable to have these hood respirators made from a transparent synthetic resin such as plexiglas or vinylite or perhaps a fireproof cellophane. The eye piece should be a large flat plate of lucite rather than the conventional double lenses. The respirator should be closely fitted to the nose and contain such filters as will efficiently filter out dust and wax.

2 The "strippers" should be supplied with clean coveralls daily, the coveralls to be laundered at the shipyard.

3 "Strippers" should wear long underclothes cleaned daily at the shipyard.

4 "Strippers" should be required to take a shower bath before going home and they should be furnished with toilet soap for this purpose.

If, for any reason, the hood respirator advocated cannot be obtained or used, a substitute not quite as good will be found in protective ointments for the face, neck and ears. The ointments should be of the type that coat the skin with a dry film that prevents the halowax from touching the skin and also prevents the soiled fingers from getting in contact with the skin. It is believed that the tetryl protective cream developed by the U. S. Public Health Service would answer this purpose. The formula for this cream is given in table 2. This preparation is now being manufactured.

The tetryl protective cream consists essentially of an alcoholic solution of shellac mixed with sodium perborate and zinc oxide. When it is applied to the skin the alcohol evaporates in about ten minutes and leaves a dry adherent coating on the skin which is difficult to remove unless it is washed off with soap and water. A somewhat similar preparation consists essentially of an aqueous solution of casein and zinc oxide and is also being manufactured.

If these ointments are used they should be applied before going to work, washed off before going to lunch, reapplied after lunch, and again washed off before going home. The clean coveralls and clean underclothes should be compulsory even if the ointment and hood are used.

It is also recommended that those workers who have halowax acne be given precautionary liver function tests, not because it is thought that they have liver damage but rather in order to make certain they have not. Liver damage does not ordinarily occur in workers handling the dry chlorinated hydrocarbon waxes. It has been found usually to occur among workers handling the molten waxes or the waxes in solution. In such instances the fumes are inhaled.

Safety directors of the shipyards were advised to report to the industrial hygiene division of the state board of health any cases of acne occurring among electricians in order that investigations may be made in time to prevent further outbreaks.

THE IDENTIFICATION AND MEASUREMENT OF THE PSYCHONEUROSES IN MEDICAL PRACTICE

THE MINNESOTA MULTIPHASIC PERSONALITY INVENTORY

J. CHARLEY McKINLEY, M.D., PH.D.

AND

STARKE R. HATHAWAY, PH.D.

MINNEAPOLIS

Many a medical man has wished for an easily applicable measuring device which would identify and characterize the psychoneurotic patient with a minimum use of the time consuming interview technique that is conventional in the psychiatric approach. One may not desire to deal with the psychoneuroses in one's practice, but the physician or surgeon is indeed insensitive to the problem or very young in the profession who has not been plagued by his inability appropriately to assess the role of the neurotic element in some of his patients.

Without wishing to belabor the topic of the neuroses unnecessarily, because much has been published on it, we should like to remind the reader of a few general points that are pertinent to this report. Competent internists have estimated variously that from 30 to 70 per cent of the ambulatory patients who appear for medical attention come primarily because of one or more complaints that turn out to be psychoneurotic in nature. It is not implicit in this statement that no concomitant organic disease is ever discovered on examination, but more frequently than otherwise the complaint is not directly ascribable to such positive manifestations as the physician may elicit. In other words, a considerable proportion of medical patients are beset by and wish for relief from emotional states rather than from bodily disease of seriously crippling importance. Furthermore, many patients with more or less severe organic disease are simultaneously suffering from undesirable emotional reactions which may definitely impede improvement or produce a worsening of the organic condition, often these patients are as much influenced for the better by reassurance, suggestion and encouragement as by those measures directed at the organic state.

In surgical practice the percentage of severely psychoneurotic patients is probably somewhat smaller. Of course, psychoneurotic patients may have surgical conditions requiring operation. Aside from emergencies, however, most experienced surgeons have learned by one or more bitter lessons that in the presence of certain types of neurosis it is indeed wise to proceed with caution and to operate only after giving appropriate attention to the attitudes and morale of the patient and his family.

Recognizing this problem and desiring to contribute to its solution, we began work in 1937 on the development of an objective personality test which is simple to use easily to interpret and conserving of time. We have chosen to name this test the Minnesota Multiphasic Personality Inventory. The statistical techniques involved

From the Division of Nervous and Mental Diseases and the Department of Psychology of the University of Minnesota.

Prepared on Work Projects Administration Official Project No. 16-17114-Sub. Project No. 379. Supported in part by a research grant from the Graduate School of the University of Minnesota.

in this study have been reported by us elsewhere,¹ the details will not be repeated at this time but only a general description of the makeup and mode of administration of the schedule and a discussion of some of its principal applications for the medical men are given in the present paper. Likewise only those portions of the inventory which deal with hypochondriasis, hysteria and reactive depression will be discussed.

III. PSYCHOMETRIC INSTRUMENT

Initially the assumption was made that statements by patients given verbally to the physician were probably not much more reliable or valid than if the same meanings were conveyed to him by sorting them on cards into the categories of "True," "False," or "Cannot Say," accordingly as the patient thinks they apply to himself. Subsequent tests of this assumption proved its truth to a very satisfactory degree. In accord with this supposition informational items with probable medical or psychiatric significance were collected; these were statements that a lay person would probably be capable of comprehending and reporting on. They were located by systematically culling them from several standard published directions for performing medical, neurologic and psychiatric examinations, from several published schedules for social and personal attitudes and from our own clinical experience. Five hundred and fifty items were retained and they constitute the basis for the Minnesota Multiphasic Personality Inventory. Each was stated in simple language, usually in the first person singular, and was separately printed on a card. An example is the item "There seems to be a lump in my throat most of the time." The groupings into which these items may be classified are as follows:

- 1 General health (9 items)
- 2 General neurologic (19 items)
- 3 Cranial nerves (11 items)
- 4 Motility and coordination (6 items)
- 5 Sensibility (5 items)
- 6 Vasomotor, trophic, speech, secretory (10 items)
- 7 Cardiorespiratory (5 items)
- 8 Gastrointestinal (11 items)
- 9 Genitourinary (5 items)
- 10 Habits (19 items)
- 11 Family and marital (26 items)
- 12 Occupational (18 items)
- 13 Educational (12 items)
- 14 Sexual attitudes (16 items)
- 15 Religious attitudes (19 items)
- 16 Political attitudes—law and order (46 items)
- 17 Social attitudes (72 items)
- 18 Affect, depressive (32 items)
- 19 Affect, manic (24 items)
- 20 Obsessive, compulsive (15 items)
- 21 Delusions, hallucinations, illusions, ideas of reference (31 items)
- 22 Phobias (29 items)
- 23 Sadistic, masochistic (7 items)
- 24 Morale (33 items)
- 25 Items primarily related to masculinity-femininity (55 items)
- 26 Items to indicate whether the individual is trying to place himself in an improbably acceptable light (15 items)

In order to locate items which would characterize a given psychoneurotic or other psychiatric type of personality deviation, it was necessary first to discover their individual frequency of placement in the "True" or "False" category for a group of "normal" individuals

These normal individuals were visitors to patients in the University Hospital who stated that they were not under a physician's care and considered themselves to be in good health. The schedule was administered to about 700 such persons. They were reasonably representative of the occupational and social levels of the University Hospital patients. As an additional check we collected inventory records on groups of students entering college and on WPA workers numbering more than 200 each. To obtain data on the placement of items by clinical groups, the items are administered to all cooperative neuropsychiatric inpatients.

An approximate idea of the method by which the various personality scales were developed can be gained by a brief review of the development of the hypochondriasis scale. A group of 50 hypochondriacal patients falling into the diagnostic category with acceptable uniformity was carefully selected on the basis of the clinical observation. The location of an item having significance in differentiating hypochondriasis from normality is a simple statistical matter. If 5 per cent of normal persons declare, for instance, that they commonly suffer with discomfort in the pit of the stomach, whereas 80 per cent of the hypochondriacal group make the same declaration, then this is an item tending to characterize hypochondriasis. In itself the item might have several other possible significances, but 60 or 70 similarly differential items identify a pattern of responses which characterizes the hypochondriacal person. Such a group of experimentally discriminative items may be spoken of as a hypochondriacal scale, since the degree to which an individual may be similar to definite clinical hypochondriacs can be determined by merely counting the items which the person answers identically with the hypochondriacal group of patients.

Although the foregoing description of the development of the scale for hypochondriasis is oversimplified, it is by such procedures that the various scales have been developed from the personality inventory. To date we have well tested scales for hypochondriasis, depression and psychasthenia and tentative scales for hysteria, psychopathic trends of the amoral type, masculinity-femininity and paranoia; several other scales are merely awaiting the appearance of sufficient clinical material to permit the statistical work for their development. Corrections have been calculated for age and sex, and the scoring has been reduced to a standard such that arbitrarily 50 represents the average score for a group of normal persons, 10 points above or below 50 represent one standard deviation from this mean value and 20 points represent two standard deviations, and so on. By the use of the standard scale, the scores for the various characteristics become comparable with one another and can be entered together on a single profile chart. This is of great convenience in the interpretation of the findings in the individual case, since the limits beyond the normal range can be expressed by a single number. Thus any score above 70 but below 80 is between two and three standard deviations above the average score of a series of normal individuals and indicates a probable abnormality for the characteristic under consideration, a score of 80 is three standard deviations above the average normal score and indicates practically certain abnormality. Scores lower than the normal average appear up to the present time to have no particular significance.

In the actual administration of the inventory, the patient is given a box containing the five hundred and

1 Hathaway, S. R., and McKinley, J. C. A Multiphasic Personality Schedule (Minnesota). I. Construction of the Schedule, *J. Psychol.* 10: 249 (Oct.) 1940. McKinley, J. C., and Hathaway, S. R. II. A Differential Study of Hypochondriasis, *ibid.* 10: 255 (Oct.) 1940. Hathaway, S. R., and McKinley, J. C. III. The Measurement of Symptomatic Depression, *ibid.* 14: 73 (July) 1942.

fifty cards and the three guide cards marked "True" "False" and "Cannot Say." His attention is called to the directions in the cover of the filing box, which read as follows:

Take out the first card in the front of the box.

Read the statement on it and decide whether or not it is true as applied to you.

If it is true or mostly true, put it in the back of the box directly behind the card that says 'True.'

If it is not usually or not at all true as applied to you, put it behind behind the card that says 'False.'

If the statement does not apply to you, or if it is something that you don't know about, put it behind the card that says 'Cannot Say.'

Do this with every card in the box.

There are no right or wrong answers.

Remember to give your own opinion of yourself.

The sorting time of the patient varies considerably, depending on his mental status. Normal, alert, intelligent persons will run through the cards in thirty to fifty minutes. Individuals with dull normal intellects will require up to an hour and a half. The moron group will need two hours or more but are usually capable of giving reliable responses. Depressed patients, especially if there is psychomotor retardation, may require several hours and several sittings for completion, and urging by an attendant may be necessary. Hypomanic patients usually give reliable responses. Patients with grossly psychotic syndromes are generally incapable of sorting the cards. However, these conditions are usually not such subtle problems from the diagnostic standpoint as are those borderline mental states in which the patient remains capable of reliable cooperation and in which the test is designed to be most useful. An accurate clerk can be readily taught to record and score the tests and a trained clerk will spend only twenty or twenty-five minutes in producing the finished profile after the patient has sorted the cards.

It is intended in this report to present several type cases which illustrate some of the interpretations that seem permissible to us on the basis of the personality profiles as derived from the inventory, the clinical features of the cases are then discussed for comparison.

REPORT OF CASES

CASE 1—A man aged 43 was admitted to the University of Minnesota Hospital on Sept. 23, 1940 for surgical attention because of a probable ulcer. In the course of the routine workup of the ulcer possibility certain psychoneurotic features impressed the cooperating internist sufficiently so that psychiatric appraisal of the case was requested.

Following a brief introductory psychiatric interview, the Minnesota Multiphasic Personality Inventory was administered on September 30 with the resultant scores hypochondriasis 87, depression 83, hysteria 78.

The scores on the other available scales were definitely at normal levels and are essentially noncontributory to this report. Thus it appeared from the inventory that the patient was severely hypochondriacal and depressed and that hysterical features also very likely were complicating the picture. The presence of these psychologic factors in the patient's illness was quickly confirmed although on interview he tended to avoid the issues relative to his emotional reactions. The hypochondriasis came out in the following statements. The patient said he was greatly concerned about his health especially in relation to his 'duodenal ulcer,' the malfunctioning of his intestine, his loss of weight and his inability to handle a full diet without great discomfort. In consequence he stated that he was depressed over the ominous future which seemed inevitable particularly in consideration of the lack of progress that he had made under a careful ulcer regimen during the previous several months. In discussing his symptoms he related his

distress during attacks, which were rather obviously hysterical. These were especially frequent in the weeks just preceding admission. They began with a sense of gas in the stomach and of pressure on the heart and in the chest. Very soon tachycardia and palpitation and then shortness of breath would appear, and the patient would become panic stricken for fear of suffocation. He would call his wife, have her open all the windows in his room and help him to a window so that he could get air. More recently he had been so weak that he had to be content to have her support him sitting up in bed during these spells. He would calm down after fifteen to twenty minutes but felt exhausted afterward.

The history of the duodenal ulcer dated back about eighteen months, when he began having rather indefinite abdominal distress. Roentgenograms taken shortly after the onset demonstrated a small duodenal ulcer, and this was confirmed later in a second series of films taken at another clinic. At the same time it was determined that, in spite of a strict Sippy regimen with large quantities of alkali, he had a total gastric acidity up to 114 degrees and a hyperchlorhydria of 100 degrees.

The medical investigation at the University of Minnesota Hospital was essentially negative except for the following findings. The patient was considerably emaciated, he had some generalized abdominal tenderness. Gastric analysis during fasting revealed 97 cc of contents with a total acidity of 107 degrees and a free hydrochloric acid titer of 102 degrees. Fractional analysis after histamine revealed a total acidity range from 67 to 103 degrees and free hydrochloric acid from 60 to 98 degrees. X-ray studies demonstrated decided hypermotility of the gastrointestinal tract. The duodenal shadows showed some irregularity suggesting duodenitis but evidences of ulcer were lacking. Routine blood and urine examinations gave negative results. There was no blood in the feces. The blood urea nitrogen, carbon dioxide combining power, blood chlorides and plasma proteins were all within normal limits.

Although the surgeon in charge felt that duodenal ulcer had not been satisfactorily excluded as a possibility, it was agreed in view of the test results that a combined medical and psychiatric approach was worth a trial and that surgical intervention could be safely postponed for a few weeks. In consequence the patient was told that his diet would be rapidly expanded and that he would be carefully observed for danger signs if they should appear. The possibility of some discomfort was admitted and it was agreed that his reports on it would be given due weight, but he would be expected to eat what was placed before him. For the first twelve days of the hospital stay, previous to the new regimen, the patient's intake averaged only 1,120 calories daily. During the next six days, with daily reassurance and urging this was increased to an average of 1,310 calories. At the end of this time his food was changed to a general bland diet of three meals a day with a calorie intake varying from 1,790 to 5,800 and averaging 3,380 daily for the remaining twelve days of the hospital stay. The patient's pulse was at first extremely variable, ranging from 76 to 140, and his temperature spiked occasionally, once going to 102 F. After the new regimen was instituted the temperature remained normal and the pulse curve steadied within the range of 70 to 90. The symptoms of abdominal distress and pressure on the heart and chest rapidly disappeared. The patient became hopeful and then cheerful, joked and conversed in animated fashion and insisted finally that he was feeling too well to remain in the hospital. He said that some business matters needed his attention and that it would relieve his mind considerably if he was allowed to return and take care of them. He was therefore discharged several days before the date previously suggested to him as a possibility. A letter from him several months later stated that he was feeling better than he had for years that he had been indulging in his favorite sports of hunting and fishing and that he was taking proper care of his business.

Just before discharge the Minnesota Multiphasic Personality Inventory was again administered and the scores were now hypochondriasis 67, depression 65 and hysteria 62.

On the day of discharge repetition of the fractional gastric analysis after histamine showed a total acidity range of 44 to 69 degrees and a free hydrochloric acid range of 38 to 65.

It is rather difficult to make a definite statement about earlier manifestations of illness, but on the patient's arrival at the University Hospital the early recognition of the psychoneurotic and reactive depressive phase of his condition provided the cue for appropriate management. The support of the psychiatric opinion provided by the Minnesota Multiphasic Personality Inventory was no small factor in convincing the surgical staff of the desirability of a psychiatric approach with rapid expansion of the diet to a normal balance and of putting off an operation which would surely have been ill advised. Then too the improvement was measured not only by weight increase, disappearance of symptoms, decreased gastric acidity and a relief of the psychoneurotic tensions but also by lowered scores to the borderline normal range of the inventory.

Incidentally it may be pointed out that many cases which clinically are diagnosed as simple hypochondriasis actually show on the inventory profile the mixed picture of hypochondriasis and hysterical tendencies with a rather high depression score. We interpret the depression as the emotional reaction to the concern over health and as the apprehension regarding an assumed hopeless future involving crippling illness.

CASE 2—A woman aged 22, unmarried, admitted to the University Hospital Jan. 22, 1942, presented a host of complaints which had been present off and on since childhood. A partial list of her symptoms included "stomach trouble," sharp pain in the flank, occasional transient episodes of blindness, painful cramps in the extremities, chest pain, "awful headaches," low back pain, "drawing feeling in shoulder and neck," dizziness, laming spells and particularly after meals, vomiting. Administration of the Minnesota Multiphasic Personality Inventory on January 26 showed a score of 93 on hysteria, 86 on hypochondriasis and 67 on depression; the other scores were clearly within normal bounds. Thus the patient appeared to be both severely hysterical and hypochondriacal and tended to be moderately depressed.

She had first been seen in the outpatient clinic in June 1940, when she complained primarily of pain in the neck, shoulders and upper extremities. Although she presented many psychoneurotic features at the time, the essential complaints referred very suggestively to possible brachial plexus involvement and the x-ray demonstration of very long cervical ribs led to a consensus favoring their removal. This was done on one side but the patient's symptoms continued after removal in almost exactly the same degree and of the same character as previously, in consequence, the opposite anomalous rib was not removed. Subsequently she continued visiting the outpatient department and failed to show any improvement. She appeared rather listless and was a continuous problem because of an occasional seemingly bona fide complaint. For example, during the past year she had noted spontaneous ecchymoses, and the cuff test showed that she did have somewhat fragile capillaries. On Jan. 1, 1942 at the gynecology clinic she complained of intermenstrual bleeding and sufficiently impressed the staff so that dilation and curettage were performed. Microscopic study showed the curettings to be normal endometrium. Since then she has abandoned her household duties, complained of extreme weakness, has been vomiting after meals and has apparently settled down to chronic invalidism.

The patient has always been frail. At the age of 14 she had jaundice, measles and mumps. At 15 tonsillectomy and appendectomy were performed. Following the appendectomy, hemianesthesia developed which persisted for about three weeks. She had German measles in 1940.

The patient completed high school at the age of 15 and was valedictorian of her class. Following graduation she served as school librarian for three years. The patient has always shown some rigidity of makeup, has had unbending religious convictions and has been comparatively sensitive. She was a diligent, conscientious worker. She tended to be withdrawn and somewhat unemotional, she did not cry at all at her mother's funeral.

The family circumstances have long been unsatisfactory. The father was described as congenial with every one except his family, in the family he was overbearing and rather despotic. He was said to have beaten the children brutally at times. He deserted the family a year before the death of his wife. The patient's mother was argumentative, disagreeable and difficult to please. Her death occurred four years before from a carcinoma. After the mother's death the patient tried to take over the household responsibilities for the five younger children but had to have constant help from another woman.

The physical examination revealed no particularly significant abnormalities. The stump of the partially removed left cervical rib could be easily palpated in the supraclavicular region. Generalized weakness of the extremities was present but was paradoxical and variable, so that it seemed apparent rather than real. Laboratory and x-ray studies were negative except for the cervical ribs.

On direct psychiatric examination she appeared preoccupied with her numerous somatic complaints and said especially that she could not keep her food down and that she had stomach (epigastric) pain. The sensorium was intact but her general knowledge seemed considerably restricted to religious topics. Her intelligence quotient was 110. It is difficult to understand how she became the high school valedictorian unless the scholastic competition was very poor in her class. Her mood was indifferent, she was inenthusiastic and her responses were somewhat inadequate. Her ideas were poorly expressed and were at times so loosely stated as to be difficult to understand. There was considerable blocking. The patient appeared somewhat restless and uncomfortable when asked leading questions. Her insight was poor. Her movements were all slow and she leaned against the wall while walking in order to obtain support. She was soft spoken and very passive in her attitude toward the physician and nurses.

Throughout her stay in the hospital she continued to have emesis after meals without preceding nausea. Some new symptoms appeared, she would let her head fall to one side and said she could not hold it erect, similarly she declared that she could not elevate one eyelid which drooped. She complained that she was unable to "think correctly." Two attempts at hypnosis were unsuccessful. For a time she remained uncooperative and wore a self-satisfied smile, for short intervals her behavior bordered on really negativistic reactions. Two weeks prior to discharge, however, she became more accessible, participated in some of the ward routine and developed a slight amount of initiative. On the decision of her guardian, who refused the suggestion of voluntary admission to a state hospital, she was discharged and returned to her home, where it was arranged that an older person would assume most of the household responsibilities.

The diagnosis was considered severe psychoneurosis of the mixed type (hypochondriasis and hysteria). While certain features were decidedly schizoid, it was felt that a diagnosis of schizophrenia was not justified at this time.

The diagnosis on the basis of clinical observation is in accord with the high scores that the patient attained on the inventory in regard to hypochondriasis and hysteria. The borderline depression score of 67 likewise seems indicative of the patient's inner thinking in consideration of the clinical syndrome, though the depression could not be spoken of as beyond that of normal.

CASE 3—A man aged 22, unmarried, entered the University Hospital on April 1, 1940 because of headache, tinnitus and tenderness of the scalp. He had been followed in the medical and neuropsychiatric clinics for about two months and was then hospitalized because he was making very little progress and intensive management seemed indicated.

The relevant scores on the Minnesota Multiphasic Personality Inventory were hysteria 84 and hypochondriasis 67. The other scores were well within normal bounds, though the depression score was slightly elevated, namely 58.

The patient's illness began in the summer of 1937, when he was working in an ore mine in Bemidji. He was unable to keep up with the amount of work the other boys of his age were accomplishing, they teased him about his low output.

After a time he began to have mild pain in the back and his appetite decreased. He began then to use these symptoms as the reason for his inability to keep abreast of the others. On returning home in the autumn he consulted an irregular practitioner, who placed him on a meat free diet which he observed for over a year. Subsequently he became anemic and because of this, he said his friends particularly the girls, began to avoid him and he turned gradually from a life of physical activity to one of concentration on his junior college studies and interest in trumpet playing. In October 1939 he first noted a dull headache which was bothersome only when he was studying. This gradually became more severe and by Christmas time he could not study at all. The headache disappeared during Christmas vacation and he worked well in school for three days after the holidays, but then it recurred so severely that he quit school entirely. The headache was persistent from that time and kept him continually at home until he appeared at the outpatient department seeking relief.

The patient had always been a fairly well liked boy, somewhat inferior physically but respected for a relatively superior intellect. He was described as kind unselfish well behaved and not suspicious. However, he desired to be a leader among the boys and he would make excuses when he could not function as the leader. His moral code has always been high. He was rather shy and afraid that people were ridiculing him for some indefinite reason.

The family was Slavonian by derivation. The father had been working on WPA, making about \$45 a month. The mother had been very solicitous of the patient and acted toward him as if he were the baby of the family needing her protection against the others.

The examination and laboratory studies revealed no serious abnormalities.

The patient's mental status in the hospital corresponded with the anamnestic data. He continually worried about his health and as to whether he would be able to return to school and become a journalist. He complained about many vague and indefinite aches and pains such as eye strain headaches, backache and anorexia. He asked 'Why must I have these headaches' and said 'These headaches are real to me and are severe even though people might not think so.' He stated that he desired to get well and go home. He was oriented in all spheres, did arithmetical problems rapidly and accurately, was well informed on general topics and displayed common sense in matters not connected with his illness. He appeared somewhat anxious sad and depressed. He declared that he understood that the headaches were functional and could define what is meant by a functional headache however, his general demeanor was not altogether in accord with this verbal insight. He talked slowly and tried to recite accurately and in detail all of his bodily complaints. On one occasion he made up a list of his complaints so that he could approximate completion of his descriptions of himself in order to make sure that he got all the topics assembled. His attitude and manner and his general appearance were usual for his social level. He was open and accessible to the examiner. On occasion he appeared relatively happy and joined in the activities in the ward with obvious enjoyment.

The patient gradually improved under the hospital care. Following a lumbar puncture a second headache developed which he recognized as quite different from his ordinary cephalalgia both slowly disappeared. Five days after the puncture he also complained of a pain in the back which he ascribed to the puncture but he located this pain two vertebral levels above the actual site. This too disappeared and then all of his complaints began to diminish until finally they were gone. He became interested in his surroundings and requested his discharge because he was feeling so well that he thought he should return home and go back to his school work. He was discharged on April 24 1940.

The final diagnosis was psychoneurosis, hypochondriasis. The notation was made that considering the rapid improvement in the hospital environment the outlook for this boy was probably good if he is not placed under much stress.

Although there is an apparent conflict in the presence of the high score of 84 on the hysterical scale and of a borderline score of 67 on hypochondriasis as contrasted with the clinical diagnosis of psychoneurosis, hypochondriasis in actuality the case draws attention to a point which has been driven home to us as a result of the use of the inventory. It has become rather obvious as our cases have accumulated that we were diagnosing as hypochondriasis two different types of case both of which present the complaint of excessive concern over presumed physical disorder.

In the one the patient expresses the belief that something is seriously threatening his health. He may be convinced as was our patient 1, that he has a gastric ulcer and that his very life is threatened by the pathologic process. Such an idea may attach itself to a variety of organs (heart lungs, kidneys or gastrointestinal tract, for example). Most of these conditions appear to grow out of tension states in which some actual bodily change such as palpitation, tachycardia, definite weight loss or muscular twitching gives the patient the notion of bodily disease. Such patients tend to test high on the hypochondriasis score.

The other type is exemplified by patient 3. In this group of individuals there seems to be an environmental setting from which the patient seeks escape or in which he has something to gain by the development of conversion symptoms. While many of these symptoms are often clearly of the conversion type, still in many instances the patient's verbalizations about them are suggestive of true hypochondriacal concern. Yet on the inventory these persons test high on the score for hysteria. Of course many of the clinical examples of the psychoneuroses are mixed both on the inventory profile and on ordinary psychiatric interpretation. Such cases may easily be mistaken clinically for simple hysteria or hypochondriasis if one does not run exhaustively through one or more detailed interviews.

CASE 4—A woman aged 25 first came to the University Hospital outpatient department in October 1936, at which time she complained of diplopia when looking to the right, blurred vision numbness and tingling of the radial portion of the right arm and hand and numbness of both legs. These symptoms had been present for only a few days. The patient said that she had had headaches all her life which were worse in damp weather and appeared mornings and disappeared during the course of the day.

Direct examination medically and neurologically was essentially negative except for a slight decrease in hearing bilaterally and on ophthalmoscopic examination slight probably physiologic blurring of the left disk margins. Most of these symptoms disappeared within a few weeks except for numbness in the finger tips. It was considered that the patient was suffering with a psychoneurosis but multiple sclerosis could not be satisfactorily ruled out.

In November 1937 she had a tooth pulled and shortly thereafter there was partial blindness in the right eye. The blindness disappeared within a few weeks but about a month later following an attack of tonsillitis the blindness recurred. Tests for visual acuity at this time revealed 1/100 in the right and 20/15 in the left eye. It was noted that she had some sinus tenderness and the ophthalmologist thought that she had an optic neuritis on the right with a central scotoma probably the result of the tonsillitis. The tag of a tonsil was removed and vision returned to 20/25 within a few weeks. She complained somewhat at the time of pain in the back or the neck. She stated that she was rather nervous.

She had no trouble then until December 1939 at which time numbness and tingling recurred in the right leg and her gait became somewhat unsteady with a tendency for her to fall toward the right side. She stated that she had had occasional

attacks of numbness and tingling of short duration in the left lower extremity and in the left hand. Examination now revealed the following findings. The knee jerks were rather strongly increased and the abdominal reflexes were absent except in the upper quadrants where they were reduced but equal. She had paresis in flexion and extension of the right leg and in plantar flexion of the right foot; she was unable to perform dorsal flexion of the foot. There was decreased sensibility to cotton and pin from the right hip downward.

The examinations were still equivocal for slightly indistinct margins. During examination she cried several times and indicated that she was not happy in her family relationships but would not discuss the matter at all. Multiple sclerosis still seemed a distinct possibility, but the staff was more impressed at this time by the emotional reactions of the patient. She returned in April 1940. The examination revealed slight nystagmus and hyperactive knee jerks. The left biceps was increased over the right. There was definite weakness of the right leg. Vibration sense seemed reduced but the patient's responses were somewhat equivocal. It was then considered for the first time that the patient definitely had multiple sclerosis. Subsequently her condition has developed into a typical severe multiple sclerosis.

During her hospital stay in 1940 the personality inventory was administered and it was somewhat surprising to find her scores all within the normal limits: hypochondriasis 62, hysteria 49, psychasthenia 42, depression 46. Evidently this patient was well equilibrated in her basic affect. Most of the symptoms

(Composite polygon comprising 690 normal cases constructed with the abscissa scored in standard scores. Above the polygon are plotted the scores of 35 patients selected at random who had been judged clinically to have depression as a prominent symptom. (Reprinted by permission of the Journal of Psychology.)

that had given rise to the impression of hysteria were actually early evidences of the disseminated sclerosis. Her peak score of hypochondriasis 62 probably represented her concern over her illness, which was indeed organic.

The findings of a normal personality profile in this patient, who was long suspected of presenting conversion symptoms, were potent evidence of the probable mistake in such an interpretation. In retrospect it is obvious clinically that multiple sclerosis was developing and that the fluctuating sensory and motor symptoms actually represented the onset of the disease. This diagnostic dilemma in differentiating hysteria from multiple sclerosis is an old one which is still bothersome even to the experienced neurologist. The inventory is thus shown to have value not only in demonstrating the presence of a psychoneurosis but also when it is within normal range, in giving precision to one's thinking in ruling out psychoneurotic reactions in cases of uncertainty.

VALIDITY OF THE INVENTORY

For the purposes of a paper like the present one, it would of course be a simple matter in a series of cases as large as the one we have accumulated to select those for report which illustrate most vividly the positive correlation between clinical opinion and inventory profile, thus leaving a more favorable impression of one's work

than would be warranted on examination of the complete data. Without getting into a detailed discussion of the statistical reliability and validity of the various scales, because this is being presented in our other papers, we should like merely to call attention to the results of one of our scores (depression), as illustrated in the chart. This is approximately representative of the other scales that have so far been developed from the inventory.

This chart shows the results in terms of a frequency polygon of scoring 690 normal persons within the age range 16 to 65 on the scale for depression. The horizontal coordinate (abscissa) gives the standard score, with 50 representing the average for the normals on this scale and 10 points representing one standard deviation, 20 points two standard deviations and so on above or below this average. The 1, 5, 10 and 50 per cent points are marked as they were obtained with the origin at the depressed end of the distribution. The percentages refer to the proportion of patients among normals scoring above each of the points indicated. Thus only 1 per cent of normal persons obtain a depression score above 82. Since there is considerable skewness to the curve these percentage points do not coincide with standard values mathematically predictable for a normal distribution curve. Above the polygon, plotted on the same standard abscissa are the individual scores of 35 depression cases which were assembled to test the validity of the depression score. Thirty-four of these test patients obtained scores higher than 50 which was the average of the normals. It is apparent that there is considerable overlap between the upper group of normals and the depressive test patients. Doubtless several factors may be operating to explain this state of affairs. On the one hand, for example, the clinical diagnosis of depression is not always necessarily correct, thus some of the test patients may have been selected with more or less clinical error involved, although all the persons used were intensively studied by the psychiatric staff. Furthermore, the reactive depressions tend to recover rather promptly, and some of our test patients were given the inventory following improvement. Such an improvement is exemplified by case 1. Then, too, an undetermined number of the normal persons were probably actually depressed at the time they were tested. This may be particularly true of a random sample of hospital visitors whose relatives or close friends are involved in serious health problems, it is to be kept in mind that our "normals" were made up primarily of such a group of visitors.

REACTION OF PATIENTS TO ADMINISTRATION OF THE INVENTORY

Objection has occasionally been raised against this kind of a technic in psychiatric cases because of an assumed mental trauma from the suggestion of symptoms or attitudes contained in some of the items making up the inventory. Indeed at the beginning of this study the first few clinical subjects were picked with the thought that those particular individuals would not be disturbed by any of the items. We soon learned, however, that the subject was indeed a rare one who showed sufficient curiosity about the matter to do more than ask a few questions. As a matter of fact, some patients with psychoneurotic tensions express relief after responding to the items because they feel that they have reported on many points to the physician about which they otherwise might not have told him. In these cases the

inventory acts in similar fashion to the conventional mental catharsis so often made use of by the psychotherapist

GENERAL COMMENT

Because of its ease of administration and its valid characterization of persons psychiatrically in quantitative terms, the Minnesota Multiphasic Personality Inventory has proved very useful in the University of Minnesota Hospital. That similar advantages would accrue to its use in general medical and surgical practice seems evident to us. The identification of the psychoneurotic individual and the determination of the degree of his hypochondriacal hysterical phobic and depressive reactions provide warning signals for the surgeon and give an indication of the need for psychotherapeutic management regardless of the presence or absence of material organic disease. The other scales which are available in tentative form, provide data concerning the person which are also of considerable psychiatric importance but discussion of these scales will be deferred for a later communication. To some extent the profile identifies not only the psychoneurotic person but also certain types of the major psychoses. As yet a satisfactory detector for schizoid tendencies is not available, but progress is being made in this direction which indicates that the inventory² contains the items necessary for detection of such trends.

SUMMARY

1 The Minnesota Multiphasic Personality Inventory is an aid in the detection, characterization and measurement of psychoneurotic trends.

2 The cases presented demonstrate the value of this technic in assessing the strength of the neurotic element in differential diagnosis in medical and surgical as well as in psychiatric practice.

3 The inventory is also valuable in ruling out psychoneurotic trends when they are absent and thus sharpens one's thinking as to the likelihood of the presence of subtle early symptoms of confusing conditions, such as multiple sclerosis.

4 The inventory is simple to use and to interpret and provides a large amount of psychiatric information about patients with a minimal amount of the physician's time.

² The sets of materials for the Minnesota Multiphasic Personality Inventory are produced and are on sale by the University of Minnesota Press, Minneapolis.

Indigestion in Wartime—Modern war waged on an unprecedented scale, has brought about conditions which have never been encountered before in the history of the world. Not only has the method of waging war been completely altered, but war today has entered every household and brought about conditions unparalleled in all the experience of the human race. The dislocation of our method of living—economic and social—apart from the immediate military problems has resulted in changes which are bound to find their repercussions in the life of every individual. The war has been responsible for uncovering latent disease, revealing weaknesses in our structural make up, and it has often demanded sudden and severe changes in our methods of living. Despite the great advances which science has made in the promotion of human health and happiness, the demands of a modern wartime economy are so severe as to threaten the life and outlook of every one seriously. The transition to wartime conditions has revealed situations which were scarcely understood in the peacetime era.—Relifuss, Martin E. *Indigestion: Its Diagnosis and Management*, Philadelphia: W. B. Saunders Company, 1943.

THE MORPHOLOGY OF TREPONEMA PALLIDUM IN THE ELECTRON MICROSCOPE

DEMONSTRATION OF FLACELLA

UDO J. WILE, M.D.

Professor of Dermatology and Syphilology, University of Michigan Medical School

AND

EDNA B. KEARNEY, M.S.

Assistant Hygienic Laboratory

ANN ARBOR, MICH.

In a recent issue of *THE JOURNAL* we published a short note on the appearance of *Treponema pallidum* when seen under the electron microscope.¹ All the preparations were specimens recovered directly from human material, for the most part primary and secondary lesions.

When the preparations were examined in the electron microscope we were unable to discern flagella.

Fig. 1—Reduction from 80,000 diameters of a portion of *Treponema pallidum* showing flagella.

despite all the evidence which points to their presence when visualized in the living state by darkfield illumination.

In a footnote in our original contribution we stated that flagella-like processes were demonstrable by careful inspection of the photographic plate. This apparent difference between what can be seen on the fluorescent screen of the microscope and what is evident on the photographic plate is due to the lesser resolving power of the fluorescent screen.

In the investigation of bacteria including *Treponema pallidum*, with the electron microscope a magnification of approximately 9,000 diameters has been found to give the best operating conditions although magnification of at least twice this amount is possible with the instrument.²

In order to study the flagella-like processes more carefully, we enlarged the photographic reproductions tenfold. The processes resemble in all respects flagella which have been demonstrated in other bacterial forms.

This work was aided by a grant from the Board of Governors of the Horace H. Rackham School of Graduate Studies.

¹ Wile, U. J., Picard, R. G., and Kearney, Edna B. *The Morphology of Spirochaeta Pallida in the Electron Microscope*. *J. A. M. A.* 119: 889 (July 11) 1942.

² Picard, R. G. *Thesis*.

occurring at different levels of the organism, but as yet we have not succeeded in finding them at the end. There is, however, every reason to believe that they occur here as well as elsewhere.

The detection of flagella-like processes in preparations of *Treponema pallidum* has been a sufficiently frequent finding to justify the assumption that they are an integral part of the organism and probably are invariably present. The technical difficulties attendant on the preparation of fresh specimen from the human host together with the frequency with which debris interferes with good reproduction, accounts for their not being an entirely uniform finding.

An electron micrograph of *Treponema pallidum* appeared shortly after our first contribution in an article by Mudd, Polevitzky and Anderson.³ In their paper flagella are shown in a photographic reproduction. The organism, however, which these authors studied came from a culture on cysteine-ascetic fluid broth which was derived from the well known Noguchi rabbit strain. The occurrence of similar processes in the organism

Fig. 2—Somewhat higher magnification showing larger number of flagella-like processes in detail.

derived from the rabbit testis and carried through culture is confirmatory evidence of our observation.

In discussing the morphologic features of the Nichols strain of *Treponema pallidum* as revealed by the electron microscope, Morton and Anderson⁴ mention flagella-like filaments and terminal filaments. These are shown and appear to be identical with those described herein. In their material, as in the article referred to by Mudd, Polevitzky and Anderson, organisms from cultures were examined. Not only are these morphologically different from those taken fresh from syphilis lesions when seen in the electron microscope, but they differ also when seen fresh in the darkfield. It is also noteworthy that organisms from such cultures after several generations are no longer pathogenic to rabbits.

However, except for the fact that the gross morphology of the organism is different from that seen in our fresh specimens, the flagella-like structures are identical with those described by us from the human strain.

THE EFFECT OF SULFONAMIDE DRUGS ON THE BLOOD PLATELETS

REPORT OF TWO CASES OF THROMBOGENIC PURPURA AND EXPERIMENTAL STUDIES ON PATIENTS RECEIVING SULFONAMIDE DRUGS

ROY R. KRACKE, M.D.

EMORY UNIVERSITY, GA.

AND

ELEANOR W. TOWNSEND, M.D.

ATLANTA, GA.

It is now a well recognized fact that the entire group of sulfonamide compounds can be added to those which may produce various disorders of the blood. Thus the rather high incidence of acute hemolytic anemia in patients receiving these drugs is now well established, as well as is the fact that the drugs are capable of producing acute agranulocytosis. Furthermore, in some instances they are capable of stimulating granulopoietic activity to the point of producing leukemoid reactions. This makes it all the more remarkable that very few reports have been presented indicating that these compounds are capable of affecting the blood platelets.

During the past eighteen months we have had an opportunity to study 3 cases in which thrombogenic purpura presumably developed because of the administration of sulfathiazole. Reports of 2 of these are incorporated in this paper, the third being omitted because of circumstances whereby we are unable to obtain detailed information.

REPORT OF CASES

CASE 1—A woman aged 40, admitted to St. Joseph's Hospital, Atlanta, Ga., Aug. 1, 1941 as a patient of Drs. Avery Dimmock and John Turner, complained chiefly of excessive vaginal bleeding during the preceding ten days. She had never had irregularity in menstruation before. During these ten days the bleeding had been more or less continuous, requiring the uninterrupted use of a large number of pads.

Physical examination revealed a decided pallor because of the excessive loss of blood. Otherwise there were no physical manifestations of importance. There were no purpuric spots on the skin nor was there any other evidence of hemorrhage except the constant oozing of blood from the uterine canal. The temperature was 102 F., the pulse rate 90 and respiratory rate 24 a minute.

Examination of the blood on admission showed 40 per cent hemoglobin and 2,800,000 red cells and 4,500 white cells per cubic millimeter with a normal differential cell count. The coagulation factors, including the coagulation time, bleeding time, clot retraction time and prothrombin time, were normal. The platelets were not counted by a direct method but were estimated on the blood film to be more than 300,000 per cubic millimeter. A tentative diagnosis of incomplete abortion was made, with a second diagnosis of a bleeding submucous uterine fibroid. The patient was given a blood transfusion and this was followed by uterine dilation and curettage. The tissue obtained showed only blood clot with no products of conception. The vagina was packed, and because of her septic course she was given 3 sulfathiazole tablets every three hours for twenty-four hours, then 2 tablets every four hours for the second two days, thus receiving 16 Gm. in three days. After three days the medication was changed to sulfapyridine, and after one day this was omitted. Twenty-four hours after the first administration of sulfathiazole the patient had bleeding in the gastrointestinal tract as shown by bloody vomitus and dark

Read before the Section on Pathology and Physiology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

tarry stools. The uterine bleeding continued unabated. She vomited blood on several occasions and after forty-eight hours there were numerous ecchymotic areas and petechial hemorrhages over the trunk, extremities and face. Examination of the blood at this time showed 2,200,000 red cells per cubic millimeter, hemoglobin 40 per cent and 3,000 white cells and the differential count was essentially normal except for a slight shift to the left in the granulocytes. The platelets were extremely few and estimated to number less than 5,000 per cubic millimeter. A careful examination of the blood showed no immature white cells indicative of a leukemic process. There was a positive tourniquet test. In addition to the admission diagnoses, a diagnosis was then made of thrombopenic purpura, presumably following the administration of sulfathiazole. The patient was given multiple transfusions but continued to run a septic course and died August 15 two weeks after admission to the hospital.

The autopsy findings included many hemorrhagic areas beneath the skin, in the mucous membranes and in the gastrointestinal tract. The kidney pelvis were filled with blood clot. About the uterus in the cul-de-sac there was a considerable amount of purulent material. The tubes were quite large, adherent to the ovaries and surrounded by inflammatory exudate. The uterus contained a large submucous fibroid tumor that was pedunculated, soft and dark red with a bleeding surface. The autopsy diagnosis was abscess of the pelvis and cul-de-sac, presumably arising from the tubes; multiple hemorrhages of the small intestine, trunk, face and extremities; and a submucous pedunculated bleeding fibroid tumor.

This report indicates that the patient's original uterine bleeding prior to admission to the hospital was caused by the fibroid tumor and that pelvic inflammatory disease accounted for her febrile course. The important feature in this case was that her blood platelets were entirely normal on admission to the hospital and she showed no evidence of blood coagulation defects to account for her bleeding; this condition developed only after a moderate amount of sulfathiazole had been administered. Consequently, it is believed that the thrombopenic purpura was caused by the administration of that drug, since no other drugs were employed during this period that could account for the sharp platelet depression.

CASE 2—A white woman aged 23 was admitted to Piedmont Hospital, Atlanta, Ga., on March 1, 1941 and died on March 5. She was a patient of Drs. H. C. Sauls and Carter Smith. On admission her chief complaint was severe backache, general malaise, nausea, vomiting and sore throat. For two days before she had passed only a small amount of red bloody urine. She had been well up until eleven days before admission at which time a sore throat developed. At that time her family physician gave her 10 grains (0.65 Gm.) of sulfathiazole every two hours for two days. On the third day she began to have pain in her back, passed small amounts of red urine and had nausea, vomiting and some swelling of the face. This continued until admission to the hospital.

Her temperature was 99.6 F., pulse rate 76, respiratory rate 18 and blood pressure 140 systolic and 90 diastolic. She was quite listless and almost semicomatose. There was no lymphadenopathy or splenomegaly. The admission diagnosis was streptococcal pharyngitis and acute hemorrhagic nephritis, presumably from sulfathiazole. On the second hospital day only 12 ounces (360 cc.) of urine was excreted and on the night of the third day numerous purpuric spots developed over the arms and trunk with uterine bleeding and expectoration of bloody sputum.

On admission to the hospital examination showed 4,300,000 red cells and 14,000 white cells per cubic millimeter, hemoglobin 13 Gm. and a slight shift to the left of the granulocytes. No platelets were seen on the stained smear. The blood coagulation factors, including coagulation and prothrombin times, were normal. Bleeding time by skin puncture was more than thirty minutes and the tourniquet test was strongly positive. The clot failed to retract and no platelets were found on the

blood film. Finally the patient had retention of nitrogenous products until March 5, the day of her death.

The patient was given no drugs other than sulfathiazole prior to the development of her purpuric disease. The Kahn test gave negative results on two occasions. Although she had received no sulfathiazole for a period of nearly one week prior to admission to the hospital, on the second hospital day sulfathiazole determinations of the blood showed 18 mg. per hundred cubic centimeters.

This appeared to be a clearcut case of severe thrombopenic purpura which presumably followed the administration of a relatively small amount (about 10 Gm.) of sulfathiazole over a period of only two days, associated with kidney damage producing retention of nitrogenous products and death. The course of events in this case was probably an original streptococcal sore throat in a previously healthy person; the administration of sulfathiazole; the development of kidney blockage, hematuria, thrombopenic purpura and finally pulmonary hemorrhages and death. Unfortunately, consent for autopsy could not be obtained.

TEN REPORTED INSTANCES

When compared to the number of cases of acute hemolytic anemia and acute agranulocytosis reported from the administration of the sulfonamide drugs, reports of thrombopenic purpura have been relatively infrequent. We have been able to find records of only 10 patients in whom thrombopenic purpura presumably developed after the administration of these drugs.

Schonberg's¹ patient was treated for dermatitis of the vulva with left inguinal streptococcal adenitis and was given 120 grains (8 Gm.) of sulfanilamide on the first day and 40 grains (2.6 Gm.) for two subsequent days. On the fourth day urticaria developed, associated with a typical purpuric rash. This patient recovered and one month later she was given one 5 grain (0.3 Gm.) tablet of sulfanilamide which was followed by a generalized urticarial eruption. In this instance the purpura presumably was not thrombopenic but developed because of widespread capillary damage.

Markel and Rike's² patient was a man aged 59 being treated with sulfanilamide for postoperative cystitis. He received 30 grains (2 Gm.) on the first day, 15 grains (1 Gm.) on the second, 30 grains on the third and 30 grains on the fourth day, at which time his stools contained gross blood with bloody urine and widespread purpura. Examination of the blood showed a depressed platelet count and delayed clot retraction with other coagulation factors normal. These authors concluded that the bleeding in their case was caused by the sulfanilamide.

Other instances of purpuric disorders have been reported following administration of sulfapyridine. Thus Aubertin and May-Darbovsky's³ patient was a white woman aged 38 being treated for arthritis with sulfapyridine. Over a period of ten days she received slightly more than 300 grains (20 Gm.). On the twelfth day there was a petechial eruption on the lower extremities and the blood platelets numbered 130,000 per cubic millimeter. The bleeding time was prolonged and the coagulation factors were normal. Cessation of administration of the drug was followed by recovery of the patient.

bleeding and diffuse purpura of the skin. After the drug was discontinued these manifestations disappeared. In this instance the purpura developed on the fourth day of treatment and the platelet count was 25,000 per cubic millimeter, associated with a leukemoid reaction to the extent of 35,000 white cells per cubic millimeter.

Hoffman's⁵ patient was a man aged 57 with a post-operative urethral discharge from a transurethral prostatic resection being treated with 60 grains (4 Gm) of sulfapyridine in one day. This was followed by bloody urine, bleeding from the gums and a hemorrhagic rash on the lower extremities. This patient was in the

hospital for several weeks under close study before the drug was given, and no hemorrhages had been present before.

Russell and Page⁶ have reported 2 cases of thrombopenic purpura resulting from administration of sulfa-

pyridine. The first report was of a Negro man aged 41 with lobar pneumonia. During a period of ten days he received 45 Gm of the drug. On the eleventh day he had generalized purpura involving the entire body, epistaxis and oozing from the gums. The platelets were estimated to be 45,000 per cubic millimeter. The patient eventually recovered. In this instance the blood sulfapyridine level was only 2.9 mg per hundred cubic centimeters.

Their second report was of a white man aged 60 with lobar pneumonia who received 18 Gm of sulfapyridine in four days, on the fourth day hematuria and generalized purpura developed. Acute hemolytic anemia with moderate leukocytosis developed and the platelets numbered less than 1,000 per cubic millimeter. He had prolonged bleeding time and normal coagulation factors. He died on the fourteenth day and bone marrow studies revealed no findings of particular significance.

Up to this time there have been reported 3 instances of thrombopenic purpura after the administration of sulfathiazole. Quick and Lord's⁷ patient was a white

Average daily variation in the number of platelets in normal subjects (solid line, details in table 2) and in patients during and after sulfathiazole therapy (broken line, details in tables 4, 5 and 6).

youth aged 19 who had been given 70 grains (4.5 Gm) of sulfathiazole for infection of the gums following extraction of teeth. Severe acute hemolytic anemia developed and on the ninth day a purpuric rash appeared over the entire body which presumably was caused by the administration of the drug, since other factors were fairly well eliminated.

The second instance of thrombopenic purpura from sulfathiazole was reported by Rosenfeld and Feldman.⁸ A white man aged 37 was being treated for cystitis, pyelitis and pyelonephritis with sulfathiazole. After taking 5.5 Gm of the drug he began to bleed from the nose and gums and also had hematuria. After the drug had been given three days his platelets numbered only 2,000 per cubic millimeter. The drug was discontinued and the patient recovered. It is interesting to note that several weeks later he was given 15 Gm of sulfathiazole in a period of five days, but after this administration there was no thrombopenia and no development of purpura.

Werner's⁹ patient developed only a cutaneous rash after receiving 14 Gm of sulfathiazole but twenty days later complete thrombopenia developed after administration of only 1 Gm of the drug. Such instances would suggest that a patient may become sensitized by the first administration of these drugs.

Thus in a summary of the reported cases of purpura caused by these drugs 2 of them have resulted from the administration of sulfanilamide, 5 from sulfapyridine and 3 from sulfathiazole. To this we add the 2 cases reported in this paper, making a total of 12.

A STUDY OF THE PLATELETS IN PATIENTS RECEIVING SULFONAMIDE COMPOUNDS

After observing 3 patients who had been treated with sulfathiazole and who subsequently had severe hemorrhages with ultimate death of all we decided to investigate the effects of sulfathiazole on the platelets of patients who were receiving this drug in routine hospital practice.

It became necessary to select a satisfactory method for the estimation of platelets and we first made platelet determinations by the three standard methods on 27 normal subjects. The platelets were estimated by the direct method, Fomic's method and Olef's method. The blood for the three tests was taken from the normal subjects at the same time.

The direct method consists of puncturing the finger, wiping away the first drop of blood, drawing diluting fluid to the 0.5 mark and then blood to the 1.0 mark in a red cell pipet and then diluting fluid to fill the pipet. The fluid used was that of Rees and Lcker and is an aqueous solution containing sodium citrate and solution of formaldehyde with a small amount of brilliant cresyl blue. After proper shaking of the pipet the counting chamber is filled and allowed to stand for fifteen minutes on damp filter paper in a petri dish. The platelets are then counted. By this method the platelet count is usually between 250,000 and 350,000 per cubic millimeter, with extremes of 200,000 and 450,000 per cubic millimeter. The average platelet count on 27 normal subjects was 277,000 per cubic millimeter.

Fomic's smear method consists of puncturing the finger and at once placing a drop of 14 per cent magnesium sulfate over the puncture before the blood begins to flow. The blood then flows into the drop until the proportion is about one part of blood to one part of magnesium sulfate solution. A small drop is then placed on a slide and a thin smear is made. The magnesium sulfate is then wiped away and an ordinary red cell count is done by the usual technique. The smear is stained with Wright's stain, the platelets are counted with the oil immersion objective until 1,000 red cells in various microscopic fields have been simultaneously enumerated. From these data the number of platelets is computed. In the group of 27 normal persons the average platelet count was 351,000 per cubic millimeter.

The third method used is known as Olef's paraffin cup method. The finger is punctured, the first drop of blood removed and a drop of diluting fluid placed over the puncture. The formula for the diluting fluid used in Olef's method is given in table 1. The blood then flows into the fluid in approximately equal amounts, and this mixture is received into a small paraffin cup which contains more of the diluting fluid. After being stirred with a paraffin coated applicator and allowed

to stand for two minutes, it is transferred to a slide in the form of a small drop sufficient to spread under a cover glass. After standing for fifteen minutes, simultaneous counts are made of platelets and red cells and the number is then computed. By this method the usual range is 350,000 to 400,000 per cubic millimeter.

After this preliminary study, we decided to use Fomic's smear method for further studies. We based this decision on the fact that this method has the

* Patients 1 through 18 and 47, 55, 59, 60 and 61 were infants and children aged 4½ months to 12 years.

† Patients 19 through 38 as they appear in the table were aged 13 to 81 years. Patients 34 through 37 were over 70 years of age.

‡ Patient 42 received sulfathiazole for two days, had chemotherapy discontinued for five days, and received a second course of the drug for three days.

§ Patient 22 was continued on sulfathiazole therapy for ten days and showed a platelet count of 300,000 on the ninth and on the tenth day.

advantages of simplicity and second of providing a permanent preparation. The results obtained by this method are within 10 per cent of those obtained by the Olef method which is probably more accurate. In any event once a method has been chosen for routine purposes it should be used to the exclusion of all others, so that platelet estimations will have comparative value. The individual counts in this study of 27 normal persons are given in table 3.

⁹ Werner, W. I. Thrombocytopenic Purpura Following Administration of Sulfathiazole. *Circulation* 26: 49 (Feb.) 1942.

Since the platelet counts may vary widely in the same individual from day to day this has to be taken into account in an evaluation of the platelet fluctuations of patients under treatment. We decided to carry out daily platelet counts at approximately the same hour of the day on 5 normal subjects for a period of ten days. The results of this can be seen in table 2.

It can be seen from this study that the platelet count may vary from 261,000 to 511,000 per cubic millimeter in a normal person and in another subject from 261,000 to 407,000 per cubic millimeter so it is obvious that great variations occur from day to day in the normal platelet count of the same individual, even when the counts are made at the same time of day with a standardized, carefully worked out technique.

Platelet determinations were begun on patients who were admitted to the hospital for various causes and who were receiving or were to receive sulfathiazole therapy for a variety of conditions. This series included 61 patients all of whom received therapy over a variable number of days usually ranging from three days to eight days, and longer in an occasional instance. In a group

* Count made in 2 case only

of 23 of these 61 patients it was possible to obtain platelet counts before the institution of drug therapy. The results obtained on each patient can be seen in table 4, and in table 5 is a summary of the results.

These results indicate that there is but little significant difference between the platelet counts of the patients before drug therapy is given and the counts obtained on the first, second and third days of therapy, but in nearly all patients after therapy has been discontinued there is a fairly sharp rise in the number of platelets. These averages are expressed in table 6 and are presented graphically in the chart.

Thus in 23 patients the average platelet count on the day before drug therapy was 275,000, on the first day of therapy nearly 300,000 and on the second day of therapy 250,000, which was below the average level in the beginning. On the day that therapy was discontinued the average platelet level was nearly 350,000 but on the following day it rose to 525,000 and then again fell back to its normal level.

The results would seem to indicate that in patients receiving sulfathiazole therapy there is a slight depression of the platelets on the second day of therapy and a decided increase in the number on the day after therapy has been discontinued. Because of the wide

variation in normal platelet counts, conclusions to be drawn from the platelet values of these 61 patients cannot be done with any degree of certainty. We can merely state that there seems to be a trend toward slight platelet depression after the institution of therapy and a considerable increase in the number of platelets after cessation of therapy. This trend, coupled with the 2 cases reported in this paper and those in the literature, indicates that in some instances platelet depression may occur to the point of thrombopenic purpura.¹⁰

CONCLUSIONS

1 There appears to be accumulating sufficient evidence to indicate that in occasional patients being treated with the sulfonamide compounds the blood platelets may be depressed to the extent of producing severe thrombopenic purpura.

2 A comparative study on normal subjects indicates that Fomon's method is sufficiently reliable and simple to be preferred as a routine procedure.

3 Daily platelet counts in normal persons over a period of ten days revealed decided variations in the number of platelets in the same individual.

4 Daily platelet estimations were carried out in 61 patients being treated with sulfathiazole and the results indicate that there is a slight platelet depression on the first day of treatment and a rather decided increase of platelets on the first day after cessation of treatment.

5 The fact that the sulfonamide compounds appear to be capable of depressing platelets in an occasional person makes it all the more important that these drugs should be used with caution only under supervision of physicians and that hematologic studies should be done frequently to determine any untoward effects on the blood.

ABSTRACT OF DISCUSSION

DR. DAVID I. MACHT, Baltimore: I was pleased with the call for a more intensive study of the morphology of the blood and other histologic changes as to the sulfonamide compounds. I would advocate not only hematologic but pharmacologic studies of the blood after the administration of these valuable therapeutic agents. I have been interested in the skin reactions after all the sulfonamide drugs because one of these resembles a fatal disease, pemphigus. Pemphigus eruptions have been described after sulfathiazole and other sulfonamides. I have made experimental studies on the subject. We gave various sulfonamide compounds to rabbits and studied the pharmacology of the blood by so-called phytopharmacologic methods—the effect on living plant protoplasm which is very sensitive to blood toxins—and it was surprising to find that after all these compounds the blood of these animals was less toxic than the normal blood of the same animals. Similar studies were made on the pharmacology of blood samples from patients receiving the various compounds and they also showed a lesser toxicity for living plant tissues than normal blood plasma. All this goes to show that after all sulfonamide drugs there are probably profound changes taking place in all the tissues and particularly in the fluid tissue, the blood, which ought to be watched in the course of chemotherapy in order to prevent dangerous accidents.

DR. HARRY J. CORPER, Denver: The sulfonamide drug especially promin, recently have attracted attention in tuberculosis the treatment of which of necessity is of long duration. We do not recognize the real value of sulfonamides as yet but

¹⁰ Since this paper was submitted for publication we have observed 2 other patients in whom severe thrombopenic purpura developed after the administration of moderate amounts of sulfathiazole, followed by death of both patients.

those who have worked on them enthusiastically and were encouraged in their action point out that there is a striking difference in the toxicity in animals and in man. This difference in toxicity is especially applicable to promin. I should like to ask Dr Kracke whether he has observed such differences and whether he can explain it.

DR ROY R. KRACKE, EMORY UNIVERSITY, GA. I am unable to give any definite answer to Dr Corper's question. The most important thing to remember about the administration of sulfonamide drugs is the knowledge on the part of all people who administer such drugs that they are capable of producing the most serious and bizarre effects on the blood cells. Also that such effects can include a depression of the thrombocytes. The drugs, of course, should not be used indiscriminately. I have been concerned in seeing some of the surgeons literally spray the peritoneal cavity with whatever agent happens to be popular at the moment. We should all realize that high blood stream levels can occur from peritoneal absorption as well as intestinal absorption.

Clinical Notes, Suggestions and New Instruments

RECOVERY FROM EIGHT GRAMS OF BARBITURATES IN ATTEMPTED SUICIDE

C. J. FRANCE, MD, MORTON BARNETT, MD, AND
F. F. YONKMAN, MD, DETROIT

Barbiturates in its various forms has been responsible for numerous suicidal attempts many of them successful. The unsuccessful cases can be attributed to either insufficient dosage ingested or to proper antagonistic therapy as is illustrated by the case reported here. In relation to the report of Hambourger¹ on the frequency of use of barbiturates as suicidal agents it behooves one to consider this class of drugs as chief offender in this modern age. Hambourger states (1939) that more than two million doses of barbiturates were sold daily in the United States and that from 1932 to 1936 the national incidence of suicide by means of barbiturates was 4.2 per cent of that for all poisons except gases, the incidence in large cities ranged from 2 to 16 per cent. These figures also behoove us to concern ourselves with the most satisfactory modern and accepted form of therapy in barbiturate poisoning.

The first clinical report of successful antagonism of phenobarbital overdosage by picrotoxin in a 3½ year old child is given by Arnett.² The rationale of his therapy was no doubt based on the experimental work in animals by Maloney, Fitch and Tatum,³ who demonstrated the restorative actions of picrotoxin and other analeptics in the presence of poisonous doses of barbiturates. Combinations of analeptics such as picrotoxin and ephedrine,² picrotoxin and metrazol⁴ or strychnine and ephedrine⁵ may often be more desirable than a single agent. Arnett's patient recovered from 0.4 Gm (6 grains) of amylal Weiss's patient from 475 Gm (71 grains) of phenobarbital and our patient from 8 Gm (125 grains) of barbituric acid derivatives, two thirds of which was pentobarbital and one third secenal. According to Fantus⁶ the fatal dose is in general,

from fifteen to thirty times the therapeutic dose. The dose of barbituric acid is nearly always fatal is about 10 Gm, that of phenobarbital from 6 to 8 Gm and that of dial about 2.4 Gm.

REPORT OF CASE

M. D., a white woman aged 32, was admitted in shock one hour after ingestion of 125 grains (8 Gm) of a mixture of soluble pentobarbital and secenal. Respirations were only 8 per minute and of Cheyne-Stokes type. Blood pressure was 60/0 and there was complete areflexia. Twenty-five mg of picrotoxin was cautiously injected throughout fifteen minutes on admission and 100 mg was then slowly infused in 1,000 cc of 5 per cent dextrose and saline solution intravenously. Shock was treated with intravenous plasma and other customary antishock therapy. At this point she was transferred to the ward. Inadvertently the stomach was not lavaged and there was no emesis at any time. In the ward picrotoxin in dosage of approximately 12 mg was injected intravenously every half hour and 300 mg of metrazol every three hours. In addition, 7½ grains (0.5 Gm) of sodium with caffeine benzoate was injected intramuscularly every three hours. The patient received

This chart presents the important features of the clinical course of a patient who was severely poisoned with barbiturates. It indicates improvement of temperature, pulse, blood pressure, respiration and other signs after treatment with plasma, dextrose in isotonic solution of sodium chloride, oxygen, picrotoxin, metrazol and caffeine. Amounts of remedial agents used and time of their administration are also noted.

3,500 cc of fluid intravenously within twenty hours. Her condition remained critical for the first eighteen hours, respirations dropped at one stage to 4 per minute, then gradually rose to 18-20 per minute. Blood pressure remained practically constant at 65-75/0 then slowly rose to normal within twenty hours especially after the eighteenth hour. On the eighteenth hour corneal reflexes were noted and subsequently there was gradual return of all reflexes. She began to groan and was aroused at the twentieth hour at which time all medication was withheld. There were no seizures or convulsions noted at any time not even the slightest twitching. It was noted after each dose of picrotoxin that breathing increased in depth and frequency but only temporarily. A similar experience was encountered with metrazol but favorable results although appearing sooner were less enduring than after picrotoxin. As the chart indicates the patient improved steadily after the first eighteen to twenty hours but for the next twenty-four hours a toxic psychosis with confusion and delirium developed.

From the Department of Psychiatry, of the Detroit Receiving Hospital and the Department of Pharmacology and Therapeutics, Wayne University College of Medicine.

⁶ Fantus Bernard. The Therapy of Barbiturate Poisoning. J. A. M. A. 115: 177 (Aug. 17) 1940.

Gradually the confusion and delirium subsided, however, and she was transferred forty-eight hours later to another hospital in good mental and physical condition.

X-ray examination had revealed no pulmonary complications, and no kidney or liver damage was noted at any time. Urinalysis was repeatedly negative. On admission to the hospital the patient's temperature was 96.4° F. It rose to 102.1° F. rectally at the time of reaction and steadily dropped to normal, the pulse followed a similar course, reaching the highest point of 130 at the time of reaction and gradually returning to normal.

COMMENT

We believe this case to be of considerable interest chiefly because it demonstrates the value of immediate and persistent combined specific therapy. Caffeine with sodium benzoate no doubt was of value here, but adequate fluid balance with plasma and repeated sustained injections of picrotoxin and metrazol should receive the most credit for recovery. Numerous cases are available which indicate that the latter two agents have restored barbiturized patients without the use of caffeine with sodium benzoate, hence the latter drug need not be used in this type of case because its action is similar to but less intensive than that of picrotoxin or metrazol. Pharmacologically, all three of these antiepileptics stimulate the respiratory and circulatory regulatory mechanisms of the medulla oblongata but also act as general stimulants of the entire central nervous system. The action of metrazol is the first to become evident, but it is not as enduring or as sustained as that of picrotoxin. There lies the virtue of a combination of the two drugs in successful treatment of barbiturate poisoning. The drugs should either be given together or preferably intermittently, one alternating with the other at appropriate intervals. Frequency of injections is determined by signs of improvement, such as increase in respiratory rate or volume, improvement in pulse and pressure, return of corneal and pupillary reflexes and skeletal muscle tone and twitchings. One can nicely titrate, if persistent and meticulous, the speed of intravenous infusion of picrotoxin and metrazol by the signs enumerated. As improvement maintains or accelerates, infusion is lessened so as to obviate the danger of central nervous system stimulation to the point of convulsions. Should the latter supervene, intravenous barbiturate in finely fractionated doses is of value. Constant observation of the patient, however, precludes the probability of increased hyperexcitability to undesirable degrees.

SUMMARY

A woman aged 32 had ingested 8 Gm. of barbiturates and recovered after a total dose of 0.477 Gm. of picrotoxin and 3 Gm. of metrazol. Caffeine with sodium benzoate and plasma with 5 per cent dextrose and saline solution were also administered.

For successful treatment of barbiturate poisoning the following points should be strictly followed:

1. Immediate antagonistic treatment with adequate and safe initial doses of picrotoxin and metrazol, dosage to depend on the condition of the patient and the amount of barbiturate ingested, if known.

2. Immediate hospitalization with prompt antishock therapy, including plasma, dextrose, saline solution, an indwelling catheter, warmth and bed stilt, and any other agent or technique which might assist in the defeat of shock and promote excretion.

3. Copious, high enemas and early gastric lavage followed by 10 to 15 Gm. of sodium sulfate solution left in the stomach for catharsis. The sodium sulfate is preferred to the depressing magnesium ion in this condition.

4. Constant observation with appropriate, sustaining and alternating doses of picrotoxin and metrazol, dosage again depending on the condition of the patient.

High estimated or known dosage of barbiturates ingested need not discourage heroic treatment, since this case represents

the upper limit of the average fatal dose stated by Fantus; but treatment must be immediate and multiple although suitable and sustained. Constant observation until recovery is mandatory.

TRANSPORTATION OF HUMAN SPERMATOZOA BY AIRPLANE FOR ARTIFICIAL INSEMINATION

FRANCES I. SEYMOUR, M.D., ALFRED KOERNER, M.D.,
NEW YORK, DAVID COSTON, M.D., MONTREAL

We report the first case of pregnancy resulting from artificial insemination in man using spermatozoa transported by airplane 500 miles. The child has proved to be a bright, normal healthy youngster.

The patient's husband gave an essentially negative history. The couple had been childless over a ten year marital period. A semen examination by the attending physician showed azoospermia. The physician then recommended cross artificial insemination as a last recourse.

Physical examination of the husband, which included a blood count, serologic test and urine studies were found to be negative. Investigation of a fresh coital seminal specimen, as well as a testicular puncture, substantiated the original diagnosis of azoospermia.

The wife's history was negative as to familial hereditary diseases. Examination, including blood studies, evaluation of gonadotropic substance, urine examination and uterosalping ography, proved essentially negative by the criteria at our disposal. The patient was accepted as a suitable case for cross artificial insemination.

In cases for cross artificial insemination it is essential to establish the husband's absolute sterility. Adjustment to the child produced by cross artificial insemination would be greatly jeopardized if a second child entered the family group resulting from a mistaken diagnosis of absolute sterility on the husband's part.

The examination of both husband and wife having been completed, the consent forms for artificial insemination which we have previously described¹ were signed and duly notarized.

Analysis of the findings corroborated the verdict of the reporting physician that the sterility of the couple was due to the husband's azoospermia. Artificial insemination with the aid of a donor was thus the only solution.

The responsibility² of selecting suitable donors is a great one. Not only must the donor's semen be normal and the donor free from venereal disease but he must have a good family history free from inheritable diseases or tendencies to disease. Furthermore, the physician must select as a donor a man whose eyes and hair have the same color as the husband's, and there should be some other common physical characteristics of the donor and husband. It would be most inadvisable to select a donor who is short and dark if the recipient's husband is tall and blond.

The selection³ of a donor entails the impersonal procurement by the physician of semen from a healthy fertile male of good character and favorable heredity—one without evidence, clinical and serologic, of ever having had either gonorrhea or syphilis. The donor must, moreover, be unknown to the couple. The donors selected should be married men whose wives begat children by them.⁴ This acts as a clinical check of fertility.

After deliberate consideration we selected a donor whose personal history was negative, whose family tree was free of

trunt of hereditary disease or dyscrasia, who personally as well as the members of whose ancestral tree, had a good educational background and a record of accomplishment in life, and who matched the husband physically. He was married and had children. On physical examination he was found free of any and all pathologic conditions. His wife knew and consented to his participation.

On April 11 we began the cross artificial inseminations. This was the eighth day of the patient's cycle. Inseminations were repeated on alternate days on six consecutive occasions. The patient returned to Canada and ten days later menstruated irregularly and scantily. Her physician made an Aschheim-Zondek test, which was negative.

The patient, in spite of being told not to expect results immediately (the first time or so), became bitterly "disappointed and depressed." In addition to being depressed (as all these patients are with the recurrence of each menstrual period) she could not afford another trip to New York, so we agreed to ship the specimens to Montreal, Canada. Her physician agreed to perform the inseminations, as he was aware of the fact that we had been shipping specimens of semen by plane for some time.

A new donor was chosen at this point because the viability index of the original donor's specimen was too short for the long Montreal trip. The second donor was matched in the same meticulous manner as the first had been.

On January 27, 29 and 30 three specimens were shipped by airplane via the regular New York to Montreal route. These specimens were unsuccessful in producing pregnancy.

The flight route between New York and Montreal via the Colonial Airlines, Inc., is at a level of 8,000 feet. Usually packages are placed in the baggage compartments situated in the wings of the plane, which are unheated and where the temperature maintained is the same as outside the plane. The weather for our next attempt was freezing. We therefore had to take the precaution that the specimen be carried in one of the moderately heated compartments of the airplane.

All specimens are placed in glass bottles embedded in cotton (acting as a cushion) and then put into a cardboard container. This in turn is sealed with regular commercial paper tape (gummed) to prevent opening in transit.

Through the courtesy and cooperation of the Canadian Customs Department, the local postmaster general waived all examinations of the parcels shipped by us to Dr. C. This of itself was very unusual, as the customs division of the Canadian government insists on chemical analysis of all fluids or products entering Canada.

February 24 we shipped a specimen which again leaked out. February 26 the successful specimen was shipped. We ship small quantities of fluid. This shipment contained 0.5 cc of fluid. Dr. C. retrieved 0.2 cc in a tuberculin syringe and inseminated intracervically. Examination showed the sperm to be very active, much more so than any of the previous specimens. On April 1 both Aschheim-Zondek and Friedman tests were positive. After an uneventful nine month gestation period a baby boy was born whose blond hair and physiognomy becomes more like the patient's husband daily. This child is over 2 years of age now.

CONCLUSIONS

1 Long range transportation of human spermatozoa by airplane can effect pregnancy.

2 Although pregnancy occurred from a single insemination on the twelfth day of the patient's cycle, persistence is a virtue which should not be forgotten when immediate success is not obtained.

3 Small amounts of semen—as little as 0.2 cc—are effective in producing pregnancy.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

OVARIES (See New and Nonofficial Remedies, 1942, p. 373)

The following dosage forms have been accepted

JOHN WIETH & BROTHER, INC., PHILADELPHIA

Ampoule Solution of Estrogens (in oil) 1 cc and 5 cc
Each cubic centimeter contains the equivalent of 5,000 international units of estrone and 0.5 per cent phenol as a preservative in corn oil.

Ampoule Solution of Estrogens (in oil) 1 cc and 5 cc
Each cubic centimeter contains the equivalent of 10,000 international units of estrone and 0.5 per cent phenol as a preservative in corn oil.

Ampoule Solution of Estrogens (in oil) 1 cc and 5 cc
Each cubic centimeter contains the equivalent of 20,000 international units of estrone and 0.5 per cent phenol as a preservative in corn oil.

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies 1942, p. 562)

The following dosage forms have been accepted

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Nicotinamide (Powder) bulk

Sterile Ampoules Solution Nicotinamide, 100 mg per cc 2 cc

Tablets Nicotinamide 50 mg and 100 mg

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Tablets Nicotinamide 20 mg, 50 mg and 100 mg

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p. 56)

The following dosage forms have been accepted

GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO.

Ampul Procaine Hydrochloride Solution 1% 2 cc
Each cubic centimeter contains 0.01 Gm in physiological solution of sodium chloride.

Ampul Procaine Hydrochloride Solution 2% 2 cc
Each cubic centimeter contains 0.02 Gm in physiological solution of sodium chloride.

PHENOBARBITAL SODIUM (See New and Nonofficial Remedies, 1942, p. 470)

The following dosage form has been accepted

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Sodium Phenobarbital Solution in Propylene Glycol 0.325 Gm (5 grains) in 2 cc ampules

LIPIODOL, 40% IODINE (See New and Nonofficial Remedies 1942 p. 306)

The following dosage form has been accepted

E. FOUGERA & COMPANY, NEW YORK

Lipiodol, 40% Iodine 20 cc neoprene-capped flask

NICOTINIC ACID-U S P (See New and Nonofficial Remedies 1942, p. 561)

The following dosage form has been accepted

PITMAN-MOORE COMPANY, INDIANAPOLIS

Tablets Nicotinic Acid 20 mg and 50 mg

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies 1942 p. 562)

The following dosage form has been accepted

PLINT, EATON & CO., DECATUR, ILL.

Sterile Solution Nicotinamide 50 mg per cc 15 cc rubber capped vial

GRAVE DIPHThERIA

During the past fourteen years there have been repeated references in the medical literature to peculiarly severe outbreaks of diphtheria most of them located in various districts of Europe. A recent review of this subject by McLeod¹ indicates not only that there are numerous records of unusually severe diphtheria but also that the results of serum treatment in many of the outbreaks proved singularly disappointing in spite of the great advance in the potency of antitoxic serums. The contrast in effectiveness of serum treatment between the incidence and severity of diphtheria in North America and in many parts of Europe especially central Europe, has been particularly striking. Does this difference depend, McLeod asks, entirely on the more enthusiastic adoption of prophylactic inoculation in the New World? How far do questions of nutrition play a part? Are there complex and insufficiently understood aspects of the development of mass immunity independent of artificial prophylaxis? Finally, are different varieties of diphtheria bacillus endowed with different epidemic potentialities involved?

There seems to have been an unwillingness to accept the most probable explanation, namely that the diphtheria in one place is different from the diphtheria in another and that it may change in the same place over a period of years. Although serum is highly valuable in the over-all picture, there may exist a variety of diphtheria in which its effect is disappointing. Some of the experiences, notably those in Australia, seem to show that with certain varieties of diphtheria in certain persons it will always be impossible to give serum in time to be of use—that is, as long as we are limited to the forms of antiserum now available. There are two other aspects of diphtheria as it has appeared in

Europe in the last ten years which reflect a change from the diphtheria at the beginning of the century. These are a shift of the main incidence to school children from those of the age group 1 to 5 years and a definite diminution of laryngeal diphtheria.

The explanation for most of the observed facts is now established and depends on the existence of three well defined cultural types of diphtheria bacillus for which the designation *gravis*, *intermedius* and *mitis* have been suggested. A small percentage of strains do not correspond closely to any of these types. These atypical strains are significant only if they appear with sufficient frequency and are found to be definitely associated with serious clinical diphtheria. Their relative proportions vary from place to place and are highest where the diphtheria is mild or of moderate severity. They are commonly found among carriers and convalescents and are more rare in association with severe or fatal illness. They have not been observed to develop an epidemic tendency. The *mitis* strains are ordinarily associated with mild diphtheria, and when they cause death, they do so mostly in infants because of obstructive phenomena and pneumonic complications. The *intermedius* strains are close to the *gravis* strains in the severity of the clinical conditions which they produce, although the over-all associated case death rate is less than with *gravis* infections. Furthermore the *intermedius* strains disappear more rapidly in convalescence and do not have the same tendency to epidemic spread as *gravis* infections. Clinically severe *intermedius* and *gravis* diphtheria are characterized by essentially toxic and hemorrhagic phenomena, myocardial weakness and pareses. The *gravis* strains possess a greater and more constant pathogenicity for animals, a deeper penetration of tissues in the human body and a greater epidemic potency.

It now seems probable that the numerous severe outbreaks of diphtheria described in Europe in 1927-1937 which were specially intractable to serum therapy were due to the *gravis* type of diphtheria bacillus. Likewise the similar serious epidemics in Britain and Australia appear to have been predominantly due to the *gravis* or *intermedius* strains. Consequently the question whether the brilliant results of prophylactic inoculation recorded in North America owe their superiority to those obtained in Europe to more comprehensive adoption and better execution or to the absence of *gravis* diphtheria in the former areas remains to be determined. Although the value of prophylactic and therapeutic inoculation has been proved beyond dispute, the present state of knowledge concerning the control of diphtheria is not conducive to any state of complacency in this country.

REFRIGERATION ANESTHESIA IN
MAJOR AMPUTATIONS

Not long ago the newly recognized importance of cooling the body in shock was discussed in these columns.¹ Refrigeration in conjunction with bloodlessness as an anesthetic in major amputations represents another application of cryotherapy. The fundamental work in the introduction of this form of anesthesia was done by Frederick M. Allen and his collaborators in the City Hospital of New York and experiments to extend the application are being continued in New York Medical College. The basic principles and the main results so far of the new method were reviewed by Allen and Crossman² at the American Congress of Physical Therapy in Pittsburgh last December.

For some time it has been known that tissues can be kept alive for many days at ice box temperature provided they are not frozen. In experiments Allen has demonstrated that the cooling of limbs and other parts with ice water or ice cracked or pulverized, down to near the freezing point say 5°C (40°F), is harmless. There is a temporary suspension of life with resumption of cellular activity as the temperature returns to normal. In refrigeration of limbs for anesthetic purposes, complete stoppage of the circulation is effected by careful application of the tourniquet. Such in brief is refrigeration anesthesia, which becomes complete after refrigeration for one to two hours. Needless to say, freezing must be avoided.

A human limb can be kept bloodless and anesthetic below the tourniquet for at least eight hours and the indications are much longer, even up to forty-eight hours without injury while the rest of the body remains warm. Amputation is done without pain, loss of blood or strength and also without shock. The nerves in the cooled, bloodless tissues cannot transmit painful impulses or harmful reactions. Toxic products are not absorbed from the refrigerated limb, and infection or its extension is prevented. Refrigeration anesthesia provides for a bloodless and shockless amputation, apparently without interfering with the healing of the stump which can be cooled as desired by gradual removal of the refrigeration. Proper cooling will restrain the circulation in the stump, prevent edema and obviate pain. So far, the reports of the results of major amputations by this method have been uniformly favorable. The mortality in amputation above the knee in diabetic gangrene has been reduced by the method.³

¹ Cooling in Shock editorial J A M A 121 432 (Feb 6) 1942. Environmental Temperature and Mortality in Burns ibid 121 132 (April 24) 1943.

² Allen F M. Experiments on Pelvic and Abdominal Refrigeration with Special Reference to Traumatic and Military Surgery. Am J Surg 55 41 (March) 1942.

³ Allen Frederick M. and Crossman L W. Suggested Use of Refrigeration Anesthesia Including War Surgery. Arch Phys Therapy 27 711 (Dec) 1942. (See also Handbook on Amputations American Medical Association 1943 p 15.)

⁴ Crossman L W. Ruggiero W F. Hurley Vincent and Allen F M. Reduced Temperatures in Surgery. II Amputations for Peripheral Vascular Disease. Arch Surg 41 139 (Jan) 1942.

Refrigeration anesthesia undoubtedly is destined to increasing use under civilian conditions as well as in war. In trauma of the limbs, for instance, which is common in war, refrigeration anesthesia will be of special service not only in amputation, but also in the control of hemorrhage, pain, progressive shock and infection during transportation of the patient when adequate treatment cannot be applied on the spot. The methods of refrigeration anesthesia are being standardized. In the New York City Hospital a controllable electric refrigeration apparatus is in use, light equipment has been devised for connection with the engine of motor vehicles and the problems of the tourniquet are receiving attention. Obviously the field of refrigeration anesthesia, besides the great variety of injuries, will include also the vascular diseases that endanger the life of limbs. Refrigeration anesthesia is an important advance in treatment. For the sake of its great practical significance the work under way in this field should be pushed ahead and the clinical application of the method expanded. Among the developments under immediate trial are refrigeration as an anesthetic for skin grafting⁵ and for the treatment of frost bite.

STERILIZATION OF THE AIR OF
CLOSED SPACES

The circumstances of modern warfare frequently necessitate the herding together of large numbers of people in air raid shelters. The control of air borne infections in confined areas has therefore become a particularly urgent problem. Several studies of this problem have been previously noted in THE JOURNAL.¹ A necessary preliminary to the scientific study of a problem of this nature is the establishment of experimental methods by which the various factors involved can be satisfactorily varied and controlled. For this purpose Edward Elford and the late Sir Patrick Laidlaw have described a method for the experimental investigation of aerosol systems formed by the atomization of suspensions of viruses into the atmosphere. They have performed observations on the physical properties of such systems and found an experimental approach to certain practical problems connected with air borne virus infections. Thus they found that mice placed in an atmosphere into which the respective virus had been atomized contract the diseases of influenza and infectious ectromelia in a manner closely analogous to naturally occurring air borne infection. This method of infection the authors believe may be used with

advantage in studying lesions of the lung microscopically and in obtaining more uniform infection of large batches of mice

In additional work also from the National Institute for Medical Research in London, Edward, Lush and Bourdillon³ describe quantitative studies carried out early in 1940 on the killing effect of ultraviolet radiation on aerosols of three different viruses—influenza A, vaccinia and herpes simplex. Using the experimental methods now established as reliable for observations of this kind, these workers showed that rapid and effective sterilization of atmospheres containing atomized particles of influenza and vaccinia viruses and probably also of herpes simplex virus, can be obtained by ultraviolet radiation of wavelength 2537 angstroms. These results support the work of Wells and his associates⁴ and indicate that "germicidal" lamps are likely to be useful in reducing the infectivity of air contaminated with particles from persons suffering from virus infections of the respiratory tract.

An additional recent contribution to the subject by Challinor⁵ of the University of Edinburgh is concerned solely with the action of hypochlorite on the total bacterial content of the air of an occupied closed room under fixed conditions of ventilation. He obtained a substantial reduction in the bacterial content of the air of an empty room infected with *Bacillus prodigiosus* (or with *Staphylococcus albus* or a diphtheroid bacillus) by means of hypochlorites introduced into the air by atomization or by spraying from an insecticide gun. The relative humidity of the air has been shown to be a factor of great importance in the effectiveness of air disinfection. In Challinor's experiments likewise effective air disinfection was not obtained at low relative humidities at temperatures ranging from 54 to 74 F. More accurate determination of the critical lower limit of relative humidity is desirable. Ultraviolet irradiation, propylene glycol vapor, as reported by Robertson and his colleagues,⁶ and now hypochlorite solution all appear to exert bactericidal and bacteriostatic effects on the atmosphere of closed air spaces. The experimental methods for controlling the factors involved are now available, so that it remains only to choose what method or combination of methods can be most effectively employed in actual practice. Possibly

the bactericidal agent may have to be varied, depending on special circumstances such as the time of year or the degree of humidity in the area. Nevertheless a partial solution at least to the problem of controlling the spread of infectious diseases in closed spaces is now at hand.

THE CONSCIENTIOUS OBJECTOR

The term conscientious objector came into use in the first world war, although reference to the problem appears in Gibbon's "Decline and Fall of the Roman Empire." The Mennonites were exempted from military service in the Netherlands in 1575. In the United States members of some religious denominations were exempted from general military service during the Civil War. At the commencement of the first world war there were in the United States, according to Hoag,¹ about 300,000 males classified as conscientious objectors. About 30 per cent of these were of military age. In June 1918 the Surgeon General's Office sent out to various camps a special form for examination of conscientious objectors. May,² in his report to the Office of the Surgeon General, presented the then available information concerning the intelligence, education, grounds of objection and social and political history of conscientious objectors. The report covered twenty camps and represented about 1,000 objectors. May pointed out that the intelligence of the conscientious objectors, as measured by the Army mental tests, was on the average, above that of the white draft of the Army as a whole. At least 97 per cent of the men had sufficient intelligence to know what they were doing. About 50 per cent were Mennonites, less than 10 per cent of these went beyond the eighth grade. The 12 per cent of the total series who reached college were either Socialists, Dunkards or Friends. The various religious sects involved, with the possible exception of the Friends, believe in the literal interpretation of the Scriptures. The grounds of objection were in general, three religious, social and political. The religious objector makes his appeal to the Bible, church creed and to conscience, the social objector to individual freedom, the political objector usually bases his objection on the ground of alien citizenship.

Stalker³ of Edinburgh reports the results of an examination of 12 persons with psychiatric states who were also conscientious objectors. They represented three types of personalities—the introverted-asocial group, the antisocial group and the mixed group. Two patients suffered from schizophrenia, 1 from a schizoid state and 1 from a mixed paranoid and manic state.

² May, Mark A. The Psychological Examination of Conscientious Objectors (Published with the Approval of the War Department), *Am. J. Physiol.* 31: 152, 1920.

³ Stalker, Harry. Conscientious Objectors with Psychiatric States, *J. Ment. Sc.* 89: 52 (Jan.) 1943.

There is thus a certain preponderance of schizophrenic types, as found by previous writers. The meager reports from continental European countries, whose laws do not provide for conscientious objectors, deal almost entirely with persons mentally involved. Thus, among 31 objectors studied by Schulthess⁴ there was only 1 sane person, 15 were psychopaths, 4 of them feebleminded and 6 schizoid. Of his own psychotic patients all were schizophrenic except 1 with dementia paralytica.

Prompt discharge from the army and appropriate institutional treatment are the effective solution of the problem of the psychopathic objector. The problem of the sane objector is much more complicated. There is, of course, no intention on the part of our government to compel the genuinely conscientious religious objector to enter the armed services, for that would amount to violation of his constitutional rights, something we must guard against even in time of war. However, the degree of sincerity of his beliefs is difficult to determine. In the first world war, of 2,100 persons 1,500 were found to be sincere objectors and recommended for farm or industrial furloughs, 219 were found to be sincere objectors to combatant but insincere as to noncombatant service, 156 were found to be sincere objectors of combatant but willing to accept noncombatant service, 15 were found to be sincere objectors to combatant service but willing to work in reconstruction hospitals and 122 were found to be insincere as to both combatant and noncombatant service.

In this war many of our conscientious objectors are young men of good education, often of good family training. No doubt the same proportions prevail in relation to religious and political objectors as in previous wars. Fortunately the problem was given attention early by the Selective Service Administration, so that today many of these boys are engaged in occupations in the field of medicine, in hospitals and in similar activities, where they are rendering a genuine service to the war effort. A number have volunteered to serve as subjects for important experiments in testing the value of life saving techniques in the services to be given to our troops in China and in the South Pacific. There are functions which the conscientious objectors can perform and for which many of them have already volunteered without demanding participation in combat.

Numerically the problem of the conscientious objector is of little importance. From an ethical point of view the problem is one of reeducation, of instilling in the individual the appreciation of his civic responsibilities and of awakening in him a feeling of national conscience and national unity.

Current Comment

BLOOD DONATIONS BY WAR WORKERS

Industrial concerns recently have been apprehensive about the effect of blood donations on war workers. A number of medical consultants to the Industrial Hygiene Foundation have concluded that ill effects need not be expected if standard procedure is followed closely. Although there may be some temporary lassitude on the part of indoor sedentary workers, eligible donors are not as a rule made weaker nor is there greater susceptibility to upper respiratory infections or other complications in the immediate period following the donation. It was the consensus that industry need not be concerned about the matter from the point of view of absenteeism or lowered production.

THE CASTORIA INCIDENT

In the week previous to April 27 the Centaur Company at Rahway, N. J., began to receive occasional reports that persons who had been given Castoria had responded with severe vomiting and nausea. The gradual accumulation of such reports led the representatives and chemists of the company, therefore, to test the product on themselves, with a result that four who tested the product also developed nausea and vomiting. Animals responded in a similar manner. The Food and Drug Administration was immediately informed and after consultation the decision was made to call in all of the product involved. Preliminary investigations failed to reveal any toxic substance or any break in the processes of manufacture. The only change in the formula has been a reduction in the sugar content as a result of the restrictions on sugar by the War Production Board. Once the decision was made to call in the product, three thousand telegrams were sent to all customers of record. Representatives of the entire Sterling Drug Products Company organization (more than two hundred in number) were instructed to call personally on all retailers and wholesalers with a view to having the product reclaimed. Radio stations throughout the nation and newspapers everywhere were requested to publish and give publicity to an announcement developed by the company. All together five hundred thousand telegrams were sent to obtain return of the product. At the time *THE JOURNAL* goes to press there seem to have been three deaths in which the physicians reporting the incidents feel that the toxicity of the product was responsible. Preliminary tests made in the laboratories of the Centaur Company and in several other laboratories which have been investigating the product failed to reveal any substance on which the responsibility can be placed. Innumerable theories have been offered including bacterial contamination, a toxin or a decomposition product of saccharin as the toxic substance yet not one of these theories has as yet been substantiated by any acceptable evidence. Just as soon as any specific cause can be determined announcement will be made.

THE LOCAL USE OF SULFATHIAZOLE IN THE NASOPHARYNX AND LARYNX

Fenton¹ and Freeman² report that the local use of sulfathiazole is highly beneficial in acute nasopharyngeal as well as laryngeal infections of streptococcal and staphylococcal nature. Fenton found that acute nasopharyngitis and laryngotracheitis due to streptococci yielded quickly to small quantities of finely powdered sulfathiazole blown into the nostrils, pharynx and larynx. He found also that gargling with a solution in a fourth of a cup of hot water of a 77 $\frac{1}{10}$ gram (0.5 Gm.) tablet of sulfathiazole often brings relief from local swelling and discomfort. He did not find that sulfathiazole had any beneficial effect on the ulcerations of Vincent's angina or the local lesions of tuberculosis or carcinoma of the larynx. Freeman found from well planned experiments that in the usual acute nasopharyngeal infections the free application of powdered sulfathiazole to the nasopharyngeal mucous membrane by means of a compressed air powder syringe quickly produced subjective and objective relief and shortened the course of the infection. The dose varied from 1 to 2 Gm. per treatment which is inexpensive, easily carried out on ambulatory patients and so far, apparently free from danger. These reports indicate that sulfathiazole may be a practically effective antibacterial agent in nasopharyngeal and probably in other similar infections. There seems to be need for a simple gargle with definite antibacterial powers for popular use. Fenton points out that rarely sensitivity to sulfathiazole may develop from its local use, an effect that needs further early and careful study. There seems to be no way by which the danger of sensitization can be determined in advance of the use of the drug.

MEDICAL RECRUITMENT FOR INDUSTRY IN INDIANA

Development and recruitment of medical personnel for industry has been a difficult problem. The physician who serves full time or nearly full time in plants engaged in the manufacture of war materials or which operate under priority ratings has been generally regarded as performing duties essential to the war effort. A dependable means of attracting new medical personnel into industrial practice has received serious consideration by the procurement agencies and by the Council on Industrial Health of the American Medical Association. An experiment is now in progress in Indiana which is intended to aid the solution of this problem. The plan calls for a preliminary two day conference at which both physician and employer may concurrently learn about objectives and procedure in modern industrial health service. Subsequently, opportunities for most intensive training will be made available to any physician who is attracted to this field or who is willing to volunteer for industrial work as

his contribution to winning the war. The general details of both programs have been organized by the committee on industrial health of the Indiana State Medical Association with invaluable assistance from the Bureau of Industrial Hygiene of the State Health Department and the Indiana University School of Medicine. The two latter agencies will provide the intensive training so arranged that very small groups can be accommodated for training to start at almost any time. Experience in Indiana already has demonstrated a better understanding of industrial health objectives and a most cooperative attitude among the principal agencies involved. The use of facilities at hand on a voluntary basis to meet an urgent situation merits a successful outcome in Indiana.

REGISTRATION UNDER THE HARRISON NARCOTIC ACT AND THE MARIHUANA TAX ACT

On or before July 1 every physician registered under the Harrison Narcotic Act or under the Marihuana Tax Act or both, must, unless he is in service, reregister with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the annual tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding \$2,000 or to imprisonment for not exceeding five years or to both. In recent years the Commissioner of Internal Revenue has given some tardy registrants the choice between paying sums by way of compromise in lieu of the penalties for their offenses or, as an alternative, accepting criminal prosecution with resultant publicity and liability to fines and possible imprisonment. This was an act of grace on the part of the commissioner, he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter. If the course that the commissioner has adopted does not produce the desired promptness in registration, he will have no recourse other than criminal prosecution to attain that result. A physician in the armed forces need not reregister. Such a physician when he receives the application form for reregistration should return it to the office of the collector of internal revenue from which it was sent, together with a statement showing that he is in the armed forces, that he does not have in his possession any narcotics and requesting that the registration number previously assigned to him be reserved. The several offices of the collectors of internal revenue have or will notify each registrant in detail of the course he should follow if he is in service. A physician on entering service should return all unused order forms to the collector's office and should dispose of all narcotics on hand, either by returning them to the wholesale concern from which purchased, if the packages are in unbroken form, or by transferring the narcotics to another physician after having obtained permission for such transfer from the office of the collector of internal revenue.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

PROCURING PHYSICIANS, DENTISTS AND VETERINARIANS IN THE FIELD

The Director of the Field Operations Branch of the Officer Procurement Service Army Service Forces, War Department, Washington, D. C., on May 1 issued the following memorandum which supplements the basic instruction on this subject contained in FT-34, Feb 27 1943. See also FT-38, FT-40, FT-42, FT-45, FT-47 and FT-52.

Lag in the Surgeon General's Program

The War Department is concerned over the lag in obtaining the number of physicians and dentists required by the Surgeon General's program for 1943.

As previously stated in FT-34, this program called for appointments at the following monthly rates: physicians 575, dentists 400, veterinarians 75.

The Officer Procurement Service now has completed three months' processing operations under FT-34. The composite results of such operations (at April 22 1943), contrasted with the three month requirement of the Surgeon General's program have been as follows:

	Physi- cians	Den- tists	Veteri- narians	Total
1 Cases received by field offices from state P & A chairmen	2 975	3 121	328	6 424
2 Less cases closed through candidates refusal and so on	1 297	691	62	2 050
3 Net cases available for completion of processing	1 678	2 430	266	4 374
4 Cases on April 22 in process or suspense	872	1 003	75	2 050
5 Cases completely processed and sent forward to SGO	806	1 427	191	2 424
6 SGO program 3 month appointment requirement	1 725	1 200	225	3 150

Of the cases completely processed and sent forward to the Surgeon General, a considerable percentage do not mature to the commissioned stage (physically disqualified, not recommended, refusal of grade, and so on). Accordingly, actual appointments of physicians during the three month period are seriously below the required level of 1,725 appointments and actual appointments of dentists are somewhat below the required level of 1,200 appointments. The veterinary appointments are to date adequate for current demands (see FT-52).

Change of Procedure in Processing of Physicians and Dentists

FT-34, paragraph 7, states the basic processing procedure in effect previous to this time. After receipt by a district office of an availability clearance form (form 97) in regard to a particular individual, the office requests the individual to complete all papers and take all steps required of him within fourteen days. If no reply is received from the individual or if he declines to act as requested, a report will be transmitted by the district office to the appropriate state Procurement and Assignment chairman. In other words, under the procedure heretofore authorized no obligation to follow up an available candidate who is unwilling to cooperate is placed on the district office which discharges its duty by promptly reporting the facts to the Procurement and Assignment Service.

With the approval of the Surgeon General and the War Manpower Commission the following change of procedures in processing physicians and dentists has been authorized. Effective immediately district offices are authorized to contact any

individual whose "availability" clearance form has been received from a state Procurement and Assignment chairman in California, Connecticut, Massachusetts, New York or Wisconsin and to urge on him his duty as a citizen to take steps to qualify for a commission. Persuasion should be exercised in a dignified manner, but district offices receiving such "availability" clearance forms are expected to do a real selling job to convince "available" persons who are apparently suitable for appointment that it is their patriotic duty to apply for a commission even though it may involve financial sacrifice. In many cases it will not involve a financial sacrifice if advantages from army pay from a tax standpoint are considered. It will be appropriate for district offices to enlist the assistance of qualified medical and dental professional societies in bringing to the person's attention his individual responsibility to his country in the existing war emergency. The Surgeon General's representatives in the service commands will be authorized to cooperate in presenting the subject to the individual. Every prompt and proper effort must be taken in the states enumerated to increase the number of physicians (and to a lesser extent dentists) to be processed and submitted to the Surgeon General under FT-34.

If, in spite of the efforts referred to, an "available" and apparently suitable individual is unwilling to proceed with the processing of his case or to make reply to the district office, the facts will be reported to the appropriate state Procurement and Assignment chairman as soon as such impossibility of processing is determined by the district office.

In other respects the standard processing procedure outlined in FT-34, paragraph 7, as amended is confirmed.

MEDICAL TRAINING PROGRAMS OF ARMY AND NAVY

Last week (p. 120) the details of the Army and Navy programs for training medical students were published in *THE JOURNAL*. Medical students who now hold commissions in the Medical Administrative Corps or in the Officers Reserve Corps and who are on inactive service for the purpose of completing their professional training may remain in that status pending completion of internship if they choose to do so and provided they fulfill training requirements. In this event they will continue to pay all of their own expenses and will also receive instruction in medicomilitary subjects. They may, however, resign their commissions and enlist in the Enlisted Reserve Corps; they will then be called to active duty at the end of the current academic period. In the event that this choice is made they become soldiers ordered to college. They have the privileges and responsibilities of enlisted men including pay and allowances, hospital care and subordination to military discipline.

Medical students in good standing in approved schools who are not now under army jurisdiction are inducted under Selective Service subsequent to June 30 1943 (they may apply for voluntary enlistment and transfer to the Enlisted Reserve Corps prior to that time) may be assigned with the least practicable delay to the Army's specialized training unit at the institution which they have previously attended.

Premedical students in the Enlisted Reserve Corps are to be called to active duty and assigned for continuation of their preprofessional or professional training. Premedical students not in the Enlisted Reserve Corps are inducted under Selective

Service subsequent to the present academic period may be, if they attain a score of 115 or better on the Army General Classification Test, if practicable, assigned for the army specialized training program.

Medical officers will be assigned to army medical units in colleges holding army contracts in order to instruct trainees in medicomilitary subjects. Medical instruction for all groups will follow the standard curriculum in force in the medical school. Only those schools which can give the standard medical training in thirty-six months elapsed time will be considered for contract. This includes, of course, the so-called five year schools. The number of men desiring premedical and medical training will doubtless, as in civil life, exceed the number of vacancies, so that disappointments are inevitable.

The navy program differs little in regard to the choice offered medical and premedical students. The published program does not discuss students taken by Selective Service. It does state that a small percentage of premedical students will be taken by the Navy from the successful applicants who passed the test given on April 2, 1943 in high schools and colleges throughout the country or who pass subsequent similar tests. Although neither the Army nor the Navy makes any promises to complete these medical programs, it may be safely assumed that all students, whether in reserve or in active enlisted status, if their scholastic and military records remain satisfactory, will be allowed to complete their medical training through the intern year.

RELOCATIONS OF PHYSICIANS

Reports received by the War Manpower Commission's Procurement and Assignment Service for Physicians, Dentists and Veterinarians show that about 600 physicians have changed their places of residence and practice in the last few months, Chairman Paul V. McNutt announced, March 30. The Procurement and Assignment Service, a division of the Bureau of Placement, makes an effort to accomplish such relocations when the medical needs of the civilian population would be better served. Figures compiled by the Procurement and Assignment Service come from forty of the forty-eight states. Of a total of 587 relocations in these forty states, 340 were directly due to action by the Procurement and Assignment Service. Five of the relocated physicians are women. A total of 214 of the 582 relocated male physicians are either over 45 years of age or, if younger, disqualified for military service. There have also been relocations in Kentucky, Delaware, Louisiana, Minnesota, Virginia, West Virginia, Oklahoma and Vermont, but the figures as yet have not been reported. In many instances, the Procurement and Assignment Service reported, the assumption of increased duties by a decreased number of physicians remaining in an area has been seen as the best solution to a community's health problem. In a number of states ingenious medical care plans have been worked out locally which enable fewer physicians to care for more civilians. Among such states are Maryland, California, Oregon, Michigan and Arkansas.

ARMY

NEW BRIGADIER GENERALS

The President sent to the Senate, May 4, recommendations that sixty-three officers of the army be given temporary promotions and among those recommended to be brigadier generals were Col. George C. Beach, Jr., M. C., originally from Topeka, Kan., and Col. Ralph H. Goldthwaite, M. C., originally of Boston.

GENERAL KING AWARDED MEDAL

Brig. Gen. Edgar King, M. C., U. S. Army, who was surgeon of the Hawaiian Department at the time of the Japanese raid on Pearl Harbor, has been awarded the Distinguished Service Medal for outstanding service in formulating plans for caring for the wounded in Hawaii. General King was responsible for preparing plans of the medical department in that area for operations in case of battle, and on Dec. 7, 1941 he carried out those plans with "such consummate skill as to save an unprecedented proportion of the wounded and elicit the admiration of the medical world." General King was born in Arkansas in 1884 and has served in the Medical Corps of the United States Army for the last thirty-six years.

JAPANESE PRISONERS

According to the Chicago Tribune the War Department informed his parents on April 27 that Capt. Max H. Bernstein, a former resident at Cook County Hospital, Chicago, is now a prisoner of the Japanese in the Philippine Islands. Captain Bernstein was commissioned in the army in January 1941 and went to the Philippine Islands in October of that year.

Relatives disclosed on April 13, according to the New York Times, that Capt. Harold W. Keschner and Capt. Samuel Bloom of Brooklyn, both members of the U. S. Army Medical Reserve Corps, are now prisoners of the Japanese. Both of these physicians interned at Mount Sinai Hospital, New York, where Captain Keschner's father is on the staff. Both of these young physicians served at Manila, Bataan and Corregidor.

THE FIVE THOUSANDTH GRADUATE

Graduating exercises were held on April 14 at the Medical Replacement Training Center, Camp Barkeley, Texas, for another class of the medical administrative corps officers candidate school, and in this large class a special honor was paid

to John E. King of Detroit, who was the five thousandth graduate since the school's inception in May 1942. In this instance the diploma was personally awarded by Brig. Gen. Roy C. Hefebower, commandant of the school, who also delivered the commencement address. Others participating in the ceremony were Col. George E. Armstrong, assistant commandant of the school, and Lieut. Col. Charles H. Discoll, M. A. C., executive officer, who administered the oath of office. Medical administrative corps officers are especially trained to carry on in the medical department the work of supply, personnel, hospital administration and training, positions which heretofore have been fulfilled by medical and dental corps officers, thus relieving the latter for duty with troops in various theaters of operation.

THE VALLEY FORGE GENERAL HOSPITAL

The Public Relations Officer of the Valley Forge General Hospital, Phoenixville, Pa., writes that through an error in his office the name of Capt. Victor H. Kugel was inadvertently omitted from the list of medical members of the staff of the hospital as published in THE JOURNAL, April 10, page 1224. Captain Kugel is the assistant chief of the general medical section. The Public Relations Officer also notes that Lieutenant Bregman's name was erroneously listed as Lieut. Gregman.

Since the article was published, the following additions to the staff have been made: Major Josiah T. Showalter, new chief of the neuropsychiatric section, vice Major Walter E. Barton, relieved; Capt. Edward R. Mountain to the eye, ear, nose and throat section, and 1st Lieut. Louis C. Burket to the outpatient department.

LIFE FOR THE WOUNDED

At a luncheon in Washington, D. C., May 18, the president of Reichel Laboratories of Kumberton, Pa., will present to the medical corps of the U. S. Army a painting entitled "Life for the Wounded," which depicts the administration of blood plasma by transfusion to a wounded soldier at the battle front. Reichel Laboratories has devised a plan whereby retail druggists may help the Red Cross increase its list of blood donors through a window display based on this painting. Every druggist using the display will receive a supply of folders explaining the routine of blood donation. Each customer is to be requested to telephone the local Red Cross blood donor service to make an appointment to give a pint of blood.

A HOSPITAL SHIP IN THE PACIFIC

The Bureau of Medicine and Surgery of the Navy has announced, according to the *Army and Navy Journal*, details concerning the care of some 4039 patients on a hospital ship during an extended period beginning with the offensive in the Solomon Islands in August 1942. Many were injured at Guadalcanal, others in battle at sea and in the air. The report was made by Comdr L K Ferguson and Lieut Comdrs R B Brown and J T Nicholson, all of Philadelphia, and Lieut Comdr H E Stedman of Ann Arbor, Mich, who remarked on the excellent condition of most of the patients taken aboard the hospital ship, especially those who had received treatment previously at field and base hospitals. The predominating injuries among the marines were wounds from fragments of shells and grenades, bullet and bayonet wounds and compound fractures. Sulfathiazole was sprayed into the simpler wounds and a pressure bandage of elastic webbing applied. The patient with a through and through wound of the leg was usually able to be up walking in four or five days from the time of the

injury and the wounds healed in a week or ten days. Not a case of infection developed in a patient treated in this manner and not 1 case of tetanus developed. All naval personnel are immunized against tetanus. About two thirds of the patients had received treatment at base and field hospitals ashore before being placed aboard the hospital ship. Of the entire group of patients treated, only 7 died, a mortality rate of 0.18 per cent.

Another report received by the Bureau of Medicine and Surgery was from Lieut George Crile Jr of Cleveland, M C, U S Naval Reserve, concerning 366 patients treated at the naval mobile hospital at Auckland and evacuated there by the previously mentioned hospital ship a day or two after the hospital had been established. The only death in this group was of a man who suffered burns over most of his body. Dr Crile said that the most striking feature of the casualties seen at this hospital was the rapidity with which the healthy young men recovered from trauma or disease, a phenomenon probably largely the result of the excellent medical care which was available to these patients from the moment of injury.

THE BROOKE GENERAL HOSPITAL

The Station Hospital at Fort Sam Houston, Texas, was named the Brooke General Hospital in honor of the late Brig Gen Roger Brooke of the Medical Corps on Sept 2 1942. The hospital, located on the large military reservation of Fort Sam Houston, consists of the old and new station hospitals with expansion units in battalion barracks located near the new station hospital building.

The construction of the buildings varies in type, but all buildings that house patients are of permanent construction. This hospital receives most of its patients from the various military posts in southwestern Texas and also acts as a station hospital for the post of Fort Sam Houston.

The commanding officer is Col George C Beach, medical corps, with the following medical officers on duty in key positions:

Lieut Col Emmett M Smith executive officer
Major Clyde Kernek hospital inspector and training officer
Major Robert J Jaehne registrar
Capt George M Hilliard receiving and disposition officer
Col Warren C Fargo assistant commandant medical department enlisted technicians school
Col John C Woodland chief of the medical service
Col John C Barch chief of the surgical service
Col Alfred R Thomas Jr chief of the laboratory service
Lieut Col Lee K Emenhiser chief of the eye, ear, nose and throat service
Lieut Col Glenn D Carl on chief of the x-ray service
Major James B Snow chief of the pediatrics section
Lieut Col Philip E Haynes chief of the outpatient service
Major Fred R Sloan chief of the gastrointestinal section

New hospital

New neuropsychiatric building

Annex number 2

Two cars of three car hospital train

Since before the first world war it has been one of the largest and most active hospitals operated by the Medical Department of the Army. It receives and treats all classes of medical and surgical cases, is designated as a pathologic center for the southern part of the United States and operates a training school for enlisted medical technicians. For six months the hospital has been operating a training school for physical therapy aides and on the 1st of July will open a school for dietitians. The hospital is also one of the few army hospitals designated for the training of interns, and a class of twelve will complete their training on June 30.

The Brooke General Hospital has a capacity of 2,225 beds at present and considerable expansion can be rapidly accomplished by taking over for hospital purposes some of the modern battalion barracks located nearby.

Major Mordecai M McDowell chief of the general medical section
Lieut Col James B Polka chief of the neuropsychiatric section
Major Edward V Swift chief of the cardiorenal vascular section
Major James B Snow chief of the pediatrics section
Capt Drury S Blair chief of the dermatologic section
Capt John T Richards chief of the infectious and contagious section
Capt Robert K Myers chief of the tuberculosis section
Major William D Tigertt chief of the pathology section
Major Vincent D Vermooten chief of the urologic section
Lieut Col Percy M Girard chief of the orthopedic section
Capt Robert C L Robert on chief of the neurosurgical section
Major William A Millington chief of the plastic surgical section
Capt Frank P Coleman chief of the thoracic surgical section
Major Herbert C Fisher chief of the general surgical section
Major Thomas E Smith chief of the rectal surgical section
Lieut Col John W Winter chief of the anesthesiology section
Major James M Siever chief of the electric section
Major Aubrey S McGee ward surgeon officers medical ward
Major Dale J Martin ward surgeon officers surgical wards
Major Samuel Millman ward surgeon women's medical wards
Lieut Col Robert G Swearingen ward surgeon women's surgical ward

NAVY

THE LOWEST NAVY VENEREAL
DISEASE RATE

The U S Navy annual venereal disease admission rate per thousand for 1942 was 29 per cent lower than for the previous year and was, it is said, the lowest in naval history. The Division of Preventive Medicine of the Bureau of Medicine and Surgery reports that the 1942 rate per thousand for the entire navy was 36, in 1941 it was 51 and in 1940 it was 80. For the continental United States the navy venereal disease admission rate last year was 22, in 1941 it was 29 and in 1940 it was 40.

The section of venereal disease control in the Division of Preventive Medicine reports that the two venereal disease posters "Fight Syphilis and Gonorrhea" and "Easy to Get—Syphilis and Gonorrhea" have proved so effective that a second and larger edition has been published.

TOUR OF INSPECTION BY
ADMIRAL McINTIRE

A tour of inspection of numerous naval activities was recently completed by Rear Admiral Ross J. McIntire, Surgeon General of the Navy. The Surgeon General was of the opinion that special commendation should go to the Naval Hospital at Corpus Christi, Texas, one of the smartest of our newer hospitals, for the excellent indoctrination course it is giving to the Waves.

The medical department of the Parris Island Station is complimented on the handling of cases of neurosis in that it is finding gainful occupation for them on the station farm and the percentage of recoveries is said to be more than 70. The Bureau of Medicine and Surgery *Weekly Gazette* of May 3 states that the commanding officer of this station paid a high compliment to the service for the fine way the dentists were putting the recruits in order.

NAVY CONVALESCENT HOSPITALS

According to the Bureau of Medicine and Surgery *Weekly Gazette* of April 19, the U S Navy is considering the acquisition of the resort hotel at Sun Valley, Idaho, and of the Hotel Avalance in Yosemite National Park, Calif., to be used as convalescent hospitals.

INSTRUCTION IN THE SPECIALTIES

A class of eight medical officers have been nominated for duty under instruction of internal medicine at the Naval Hospital, Philadelphia, and six medical officers have been assigned to the Mayo Clinic, Rochester Minn. for advanced instruction in general and reconstructive surgery.

COMMANDER HOGAN AWARDED MEDAL

The Secretary of the Navy Frank Knox, presented to Comdr. B. W. Hogan (MC) U S N, the Navy and Marine Corps Medal on April 15 for outstanding heroism in treating injured survivors of the U S S *Hasp*, even though severely burned and injured himself.

NEW BUILDINGS FOR NAVAL MEDICAL
SUPPLY DEPOT

The Naval Medical Supply Depot Brooklyn, has acquired new buildings and property at Edgewater, N. J., which will be known as the annex of the Brooklyn depot. It has an area of 29 acres and buildings which will provide 234,600 square feet of storage space with ample rail facilities, power plant and garage. When the present construction is completed the total storage space will be approximately 600,000 square feet.

MISCELLANEOUS

OFFICE OF DEFENSE HEALTH AND
WELFARE SERVICES ABOLISHED

The President by Executive Order 9338, dated April 29, has abolished the Office of Defense Health and Welfare Services and has transferred to the Federal Security Agency the functions, duties, powers, personnel, property, records and funds of that office and of the Health and Medical Committee and the other advisory committees and subcommittees appointed by the director of that office. The transferred functions, duties and powers will be hereafter administered under the direction and supervision of the Federal Security Administrator through an office to be established by him and to be known as the Office of Community War Services or through such other agency, officers and persons in the Federal Security Agency as he shall designate and in such manner as he shall direct.

WARNING—SUBSTITUTES FOR GLYCERIN

The present shortage of glycerin and the necessity of issuing available supplies for essential war needs has made it necessary to deny the use of glycerin in many instances. Many former users of glycerin who are now unable to secure supplies are using substitute materials when they are available.

In a recent memorandum the United States Department of Agriculture discussed the reasons for its inability to allocate glycerin to all uses as well as the methods for obtaining glycerin for approved end uses. The need of working out substitutes when possible also was mentioned. In using substitutes all consumers must investigate the toxicity of the substitute, since certain substitutes are definitely toxic. Among these toxic substitutes are ethylene glycol, diethylene glycol (diglycol), carbital and polyethylene glycol, and under no circumstance should these or other toxic substitutes be used in any product whether

food, drug or cosmetic which is likely to be taken internally or otherwise absorbed by external application.

The Department of Agriculture points out that a number of proprietary glycerin substitutes have been offered for sale. Before they are used, inquiry should be made of the manufacturer in order to determine whether or not any of the compounds mentioned or other toxic substitutes are present. When in doubt as to the use of any of these substitutes in food, drug or cosmetic preparations, one should inquire of the authorities in charge of administering the Food, Drug and Cosmetic Law.

USE OF COPPER IN RUBBER
HOSPITAL SUNDRIES

Use of copper in hot water bottles, syringes, ice caps, bulbs and similar supplies commonly referred to as "rubber hospital sundries" is restricted, but not completely prohibited, by the terms of Copper Order F-9-e, the Copper Division of the War Production Board pointed out on April 22. In brief, these are the applicable rules governing the use of copper and copper base alloy in such products. If the copper material was acquired before June 30, 1942 it may be used in manufacturing assembling or finishing rubber hospital sundries only on orders rated AA-4 or higher. However, a manufacturer may apply to WPB on Form PD-426 for authorization to fill lower rated orders. If the copper material was acquired after June 30 it may be used in the manufacture of the hot water bottles and other utensils without a preference rating, subject to the following conditions. The copper material may not be used where the use of a less scarce material is practicable, and the use of more copper material, or copper of a higher grade, than is necessary for the proper operation of the article to be manufactured is prohibited.

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 10 30 p m Saturdays over Station WMAQ.

The titles and guest speakers for the next four programs are as follows:

May 22 Fla h Burns
Speaker Rear Admiral Ross T McIntire M C Surgeon General
United States Navy
May 29 Sick Call
Speaker Brig Gen John M Willis Commanding General Camp
Grant Illinois

June 5 Doctors for Tomorrow

Speaker Brig Gen Fred W Rankin President of the American Medical Association

June 12 Medical Discoveries in Wartime

Speaker Morris Fishbein M D Editor of THE JOURNAL

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled 'Before the Doctor Comes' will be on the air every Thursday afternoon at 2 45 up to and including May 27. Mrs June Merrill will interview Dr W W Bauer, Director, Bureau of Health Education, on common home health problems. The titles for the last two programs are

May 20 Nervous Habits
May 27 Immunization

WOMAN'S AUXILIARY

WOMAN'S AUXILIARY TO THE AMERICAN MEDICAL ASSOCIATION

Twenty-First Annual Meeting, June 7-9, 1943
Drake Hotel, Chicago

A most cordial invitation is extended to all Auxiliary members and the wives of physicians attending the American Medical Association meeting to attend the sessions of the twenty-first Annual Meeting of the Woman's Auxiliary to the American Medical Association. Mrs Rollo K Packard is chairman of the Chicago Committee.

Headquarters will be in the Grand Ballroom of the Drake Hotel, where all meetings will be held. Please register early and obtain your badge and program. Tickets may be purchased at the registration desk.

All meetings will convene at the time scheduled. Please be prompt.

Registration, in the French Room Foyer

Sunday, 2 to 4 p m
Monday, 8 30 a m to 4 p m
Tuesday, 8 30 a m to 4 p m

Preconvention Meetings

SUNDAY, JUNE 6

3 p m Nominating Committee meeting Parlor H (east mezzanine), chairman Mrs Robert E Fitzgerald
7 p m Finance Committee meeting chairman Mrs Harold F Wahlquist

PROGRAM

MONDAY, JUNE 7

9 a m Meeting of the Board of Directors Parlors F-G (east mezzanine), Mrs Frank N Haggard presiding
12 30 p m Luncheon in honor of the past presidents of the Woman's Auxiliary to the American Medical Association Gold Coast Room. Tickets \$2.25 (subject to market conditions and food administration regulations). Guest speaker Dr Frank P Hammond, chairman of the Advisory Committee of the Woman's Auxiliary to the Illinois State Medical Society. Subject: Doctors' Wives—Medicine's Closest Ally.

Convention Meetings

MONDAY, JUNE 7

2 p m Opening meeting of the House of Delegates of the Woman's Auxiliary to the American Medical Association Grand Ballroom (lobby floor east). Mrs Frank N Haggard President.

Invocation Rev Harrison Ray Anderson, Fourth Presbyterian Church, Chicago

Address of Welcome Hon Edward J Kelly, mayor of Chicago

Tribute to Deceased Members

Introduction of Mrs Rollo K Packard chairman of the Chicago Committee

Presentation of the President-Elect Mrs Eben J Carey

Minutes of the Twentieth Annual Meeting Mrs Carlton F Potter, Secretary

Roll Call Mrs Carlton F Potter

 Report of Bulletin Circulation and Central Office Miss Margaret Wolfe
 Reports of state presidents
 12 30 p m Luncheon in honor of Mrs Frank N Hayward, President, Gold Coast Room Tickets \$2.25 (subject to market conditions and food administration regulations)
 Guest Speakers Brig Gen Fred Rankin, President, American Medical Association, Dr James E Phillips, President-Elect, American Medical Association, Dr Morris Fishbein, Editor, THE JOURNAL and HYGIENE
 2 p m Afternoon session
 Report of Nominating Committee Mrs Robert E Fitzgerald
 Election of Officers

Installation of Officers and Presentation of President's Pin Mrs R L Mosman
 Inaugural Address Mrs Eben J Carey
 Minutes Mrs Carlton F Potter
 8 p m Opening Meeting of the House of Delegates of the American Medical Association, Palmer House, Grand Ballroom
 Members of the Woman's Auxiliary and guests are welcome

WEDNESDAY, JUNE 9

10 a m Executive Committee Meeting, Parlors F-G Mrs Eben J Carey, presiding
 10 30 a m Board of Directors Meeting, Parlors F-G Mrs Eben J Carey, presiding
 Dr James P Simonds, professor of pathology, Northwestern University Medical School, will speak on "The Effect of War on Medicine"

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—Public hearings have been started by the Senate Committee on Education and Labor and by the House Committee on Interstate and Foreign Commerce, respectively, on S 983 and H R 2326 companion bills to provide training for nurses for the armed forces, government and civilian hospitals, health agencies and war industries through grants to institutions. S 875 has been reported to the Senate by the Senate Committee on Education and Labor, a bill to provide for the preparation of high school students for wartime service, to be known as the Victory Corps Act of 1943. A federal appropriation of \$912,513 for the fiscal year 1943 and of \$8,484,377 for each fiscal year thereafter is proposed for making payments to states which have submitted plans approved by the Commissioner of Education. Among other things, a state plan must make available appropriate medical examinations of students who may be inducted into the armed forces or who may be preparing for other essential war services. A total of \$3,009,300, it is contemplated will be allotted annually for medical examinations. The authorizations contained in the bill will expire six months after the end of the war. S 885 has passed the Senate, a bill to establish a Civilian Supply Administration. The administrator of that administration it is proposed, will be authorized, among other things, to ascertain the quantities and types of goods and services (including but not limited to food, clothing, shelter, fuel, transportation and medical care) necessary to keep the civilian population healthy and functioning effectively and to apply to the appropriate government agencies which allot resources for military, naval, export and civilian purposes for the amounts and types of manpower, materials, facilities, transportation and other resources determined by him to be essential to produce and distribute the necessary goods and services. H R 2536 has been reported to the House by the House Committee on Education, a bill to enact the Vocational Rehabilitation Act. This legislation will be administered, it is proposed, by the Federal Security Agency. Among other things, it provides that the federal government will pay one half of necessary expenditures for designated rehabilitation services rendered under state plans to disabled individuals found to require financial assistance, including corrective surgery or therapeutic treatment necessary to correct or substantially modify a physical condition which is static and constitutes a substantial handicap to employment, necessary hospitalization, in no case to exceed ninety days, in connection with corrective surgery or therapeutic treatment, medical examination where necessary to determine eligibility for vocational rehabilitation, and such prosthetic devices as are essential to obtaining or retaining employment.

Bills Introduced—S 1033, introduced by Senator Clark, Missouri, and H R 2554, introduced by Representative Van Zandt, Pennsylvania, provide that all the provisions of existing law and of veterans' regulations applicable to veterans of World War I be extended to include veterans of the present war and their dependents.

STATE MEDICAL LEGISLATION

California

Bill Introduced—A 1928, to amend the health and safety code, proposes to eliminate therefrom the existing proviso that a drug shall be deemed to be misbranded if it is sold at retail for use by man and contains any quantity of amidopyrine, emclophen, sulfanilamide or any of its preparations, compounds or derivatives, unless it is sold on a written prescription signed by a member of the medical, dental or veterinary profession who is licensed by law to administer such drug and its label bears the name and place of business of the seller, the serial number and date of such prescription, and the name of such member of the medical, dental or veterinary profession.

Bills Enacted—S 547 has become chapter 214 of the Laws of 1943. To amend the premarital examination law, it provides that certificate forms furnished by other states having comparable laws and by the United States Army or Navy for military personnel may be accepted. A 6 has become chapter 254 of the Laws of 1943. It amends the osteopathic practice act by eliminating the existing requirement that osteopaths, at the time of the annual renewal of their licenses, must present satisfactory evidence of the completion, during the preceding year, of a minimum of thirty hours of professional educational work as approved by the osteopathic board. A 1936 has become chapter 325 of the Laws of 1943. It amends the penal code by making it unlawful for any person to sell, furnish or give away any veronal, barbital (acid diethylbarbituric) or other barbituric acid derivative and compounds thereof, except on the order or prescription of a physician and surgeon, dentist, chiropractist or veterinary surgeon duly licensed to practice in the state of California. Such prescription shall not be refilled without the order of the prescriber except that a prescription for phenobarbital or any preparation, mixture or compound of phenobarbital may be refilled.

Connecticut

Bill Enacted—H 1265 has become chapter 166 of the Laws of 1943. It makes both husband and wife liable for the reasonable and necessary services of a physician and for hospital expenses rendered to the husband or wife or a minor child living with the parents.

Illinois

Bills Introduced—S 376 proposes the granting annually of cash awards of \$500 and \$250 to physicians in the employ of the department of public welfare other than those employed in the Illinois Neuro Psychiatric Institute and the Institute for Juvenile Research, for the purpose of stimulating creative research in the field of mental illness, its nature, causes and treatment. The awarding of these prizes would be under the direction of, and according to rules established by, the department of public welfare. H 512, to amend the law relating to premarital examinations, proposes that the required certificate may be executed by any duly licensed physician, rather than just by a duly licensed physician in this state as is presently required.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

State Medical Election—Dr Frederick W Wilkerson, Montgomery, was elected president of the Medical Association of the State of Alabama at its recent annual meeting. Other officers chosen include Drs Benjamin W McNease, Fayette, and William Hill McCaslan, Union Springs, vice presidents. Dr Douglas L Cannon, Montgomery, continues in office as secretary-treasurer, his term not expiring until 1945. The 1944 meeting of the association will be held in Montgomery, April 18-20.

CALIFORNIA

Case of Spotted Fever in Siskiyou County—The first case of Rocky Mountain spotted fever in Siskiyou County was reported April 1. Newspapers stated that a woman residing in Horse Creek contracted the disease and was dismissed as improved from the Siskiyou County General Hospital, Yreka, after thirty-seven days.

New Hospital in Vallejo—Ground was broken on April 5 for the Vallejo Community Hospital, a 262 bed institution to be erected in one hundred and eighty days by the Emergency Operations Unit of the Public Buildings Administration of the Federal Works Agency at a cost of \$1,100,000. All buildings will be of wood construction because other materials are not available, but each wing will be cut off from the corridors by fire walls. Construction will be one story because elevators are not available.

Autopsy Surgeon Needed—Applications are being accepted by the Los Angeles County Civil Service Commission for the position of autopsy surgeon for work in the Los Angeles County Department of Coroner. The salary is \$4,800 a year. There will be no written examination; candidates will be rated on their professional training and experience and their ability and personal suitability for the work as evidenced by investigation or interview. Applicants must be between 21 and 55 years of age with an M.D. degree from an approved medical school and have completed at least one year's internship in an approved hospital and two years of professional experience in the pathology laboratory of an accredited hospital, medical school or commercial laboratory or in a public agency. Applicants over 55 years of age may file for "duration" work. Applications must be filed on or before May 24 in the office of the civil service commission, room 102, Hall of Records, Los Angeles.

FLORIDA

State Medical Election—Dr John R Boling, Tampa, was named president-elect of the Florida Medical Association at its annual meeting in Jacksonville, April 16, and Dr Eugene G Peek, Ocala, was installed as president. Other officers include Drs Louie M Limbaugh, Jacksonville, Lloyd J Netto, West Palm Beach, and Carl E Dunaway, Miami, vice presidents. Dr Shaler A Richardson, Jacksonville, was reelected secretary-treasurer for the nineteenth year. Stewart G Thompson, DPH, Jacksonville, was confirmed to his post as managing director, which he has held for eighteen years.

MARYLAND

Study of Absenteeism—The labor-management advisory committee in Baltimore has just begun an absenteeism program which will provide specific information about job absences at each plant. A separate record will be kept for each worker; the data to be made available to the worker's selective service board.

Personal—Dr Joseph Earle Moore, Baltimore, was given an honorary life membership in the American Social Hygiene Association recently. Dr Robert U Patterson, dean of the University of Maryland School of Medicine and College of Physicians and Surgeons and superintendent of the University Hospital, Baltimore, has been appointed consultant to the Baltimore City Health Department.

Night Health Service—To meet the health problem created by the rapid growth of population, the Baltimore Department of Health has expanded its baby clinics, venereal disease clinics and tuberculosis clinics and has rearranged hours so that they are open nights to serve war workers. In addition, its staff of inspectors has been increased and is campaigning vigorously against insanitary housing. According to the Office of War Information the city's health problems have been increased because of the large percentage of persons now coming to Baltimore from more isolated rural areas in North Carolina, West Virginia, Kentucky and Tennessee who lack the knowledge of and interest in health protection that most urban residents possess. At the end of 1941 toxoid inoculation against diphtheria had been given to 81 per cent of the children under 5 in Baltimore and to 94 per cent of those between 5 and 9. This percentage, which has been rising steadily for years, is now decreasing because of the newcomers; it was stated.

MASSACHUSETTS

Dr Wilinsky Awarded Civic Medal—Dr Charles F Wilinsky, executive director and superintendent of the Beth Israel Hospital, Boston, on April 12 was awarded the annual medal of the Boston City Club for distinguished civic service. Dr Wilinsky is chief medical officer of the Boston Public Safety Committee and his selection for the medal was "the outcome of his work in organizing the medical section of the city's civilian defense effort, and for his work during the Coconut Grove disaster." The gold medal is presented each year to the citizen adjudged by the club to have rendered the most outstanding civic service to greater Boston. Editorial comment was made in all the local papers concerning the presentation.

Changes in Program of Dental Medicine—Certain changes have been announced in the dental program at Harvard University now being carried forward by the new school of dental medicine, including the reduction of the course from five years, as set in 1940, to four academic years, or three calendar years under the accelerated wartime schedule, award of the D.M.D. degree only on completion of the course, and the permission of students successfully completing the course for the D.M.D. to register subsequently in the medical school and qualify for the M.D. degree on the completion of one and a half additional academic years or one additional calendar year in the medical school. According to an official release there will continue to be no segregation of candidates for the D.M.D. degree from the candidates for the M.D. during the first two academic years. Students in the school of dental medicine will be required to meet the same standards of scholarship that are demanded of medical students, and the successful completion of the courses in the first two academic years of the medical school curriculum will be necessary before the candidate for the degree D.M.D. can enter the third year in the school of dental medicine. During the first two years discussions in the field of dentistry will be presented to the combined class so that students planning to enter this field will be able to orient themselves for the third and fourth sessions. When the activities of the Harvard School of Dental Medicine were launched with funds of \$1,350,000 in July 1940 the plan provided for a five year course, at the end of which the successful student should be given both the M.D. and the D.M.D. degree. In an official statement James B Conant, president of the university, stated that it was predicted from the start that difficulty would be encountered under the plan because a man enrolled for the joint degrees of M.D. and D.M.D. might shift his interest to some other branch of medicine rather than continue with the course headed for D.M.D. "The prediction of difficulty was accurate. Whether or not this would have been the case except for the war no one can tell. Instead of the course of five academic years which we planned, army and navy regulations now make mandatory the limitation to three calendar years in courses leading to the medical and dental degrees," President Conant said.

MINNESOTA

State Tuberculosis Unit—The establishment of a tuberculosis control unit in the state division of public institutions has been announced. Dr Herbert A Burns, medical superintendent of the Minnesota State Sanatorium at Ah-gwah-ching has been placed in charge of the new unit. He has been succeeded at Ah-gwah-ching by Dr Francis F Callahan, formerly medical director of Pokegama Sanatorium, Pokegama.

Sentenced for Fraudulently Obtaining Morphine Prescriptions—On April 21 Alva George, 43 years of age, was found guilty by a jury in the District Court of Hennepin County of obtaining morphine prescriptions by fraud and sen-

tenced not to exceed two years in the Women's Reformatory at Shakerlee. The investigation preceding her arrest disclosed that the defendant was obtaining morphine prescriptions surreptitiously from seven physicians. At the trial, and prior to sentence being imposed counsel for the defendant severely criticized the medical profession claiming that the defendant was given narcotic prescriptions without any reason.

NEW YORK

Institute for Family and Child Care Services—Vassar College, Poughkeepsie will conduct its second institute for family and child care services in wartime, July 1-30. The institute constitutes a training and demonstration center for parents, teachers, social workers and other professional workers. Community organizations, child care out of school programs, personality development and preparation for service in China will constitute the two main fields of study for the institute.

New York City

The Harvey Lecture—Dr. Virgil P. W. Sodenstricker, professor of medicine, University of Georgia School of Medicine, Augusta will deliver the eighth and last Harvey Society Lecture of the current series at the New York Academy of Medicine on May 20. His subject will be "Nutrition Under Wartime Conditions."

Physician Fugitive from Prison Term—Dr. Louis G. Small, who is said to be under a Sing Sing sentence of three to six years on his General Sessions conviction for operating an abortion mill with two other physicians is the subject of a countrywide search ordered on April 19 by District Attorney Frank S. Hogan, the New York *Times* reported. Dr. Small was to have appeared before Judge Jacob Gould Schmucker Jr. on April 19 for a new commitment to Sing Sing on the sentence after having lost an appeal in the Appellate Division. The *Times* reported that the casualty company which had furnished \$12,000 bail for him, pending the outcome of the appeal, had received word from Dr. Small from Fismun, Ga., that he would not return and the court issued a bench warrant for him. The *Times* further reported that after he had been found guilty of nine counts of abortion and one of conspiracy in the operation of an abortion mill at 116 East Sixth-Third Street Dr. Small obtained a writ of reasonable doubt from Justice Samuel Nunn in the Supreme Court. The bail was accepted for him at the time. The appellate division handed down the decision affirming the conviction, April 16. It was stated:

Answer Criticisms on Alien Admissions to Membership—The committee on membership the comitia memora, and the society itself can exclude candidates for membership only on the grounds of individual disqualification. The Medical Society of the County of New York stated April 24 in reply to "certain" criticisms made on the admission of a large number of foreign physicians to membership in the society. According to the New York *Times*, the comitia memora said that "they have no power, nor have they the desire, to discriminate against an individual candidate because of race, creed, color or national origin." It was emphasized that "all races and all nations have contributed to medical progress and that in organized medicine, at least, the profession remains a fraternity from which no deserving practitioner, whatever his origin, is barred. On practical grounds alone the comitia memora long ago recognized the desirability of bringing qualified foreign graduates into the society, thereby subjecting them to the same ethical restraints as govern native physicians. This is assuredly preferable to leaving large, unassimilated professional groups outside the jurisdiction of organized medicine," the report stated.

Fund for New Science Fellowships—Charles L. Mayer has given funds to the Committee on Medical Education of the New York Academy of Medicine to provide four fellowships of \$2,000 each for research with a view to advancement of knowledge in the following subjects:

- The use of choline and other lipotropic factors in the prevention and treatment of fatty infiltration of the liver and hepatic insufficiency.
- The action of ingested choline lecithin, methionine and inositol on pre-cancerous lesions and disorders associated with neoplastic disease.
- The effects of riboflavin, certain amino acids, and casein on the development and growth of cancer.
- Study of the relationship between precancerous lesions of the mouth, hepatic insufficiency and gastrointestinal disorders.

Applications for consideration in these awards should state the name of the individual who will conduct the research, the name of the laboratory or institution in which the work will be conducted and the special qualification, interest or attributes of the investigator and institution which may justify the award. If the applicant has already conducted research in the specified field for which the award is sought, this fact should be stated

and reprints of publications in this work by the author should accompany the application together with any other facts or information deemed pertinent. An approval of the director of the laboratory should accompany the application, if the application is not made by the director. All applications should be sent in triplicate to Dr. Mahlon Ashford, secretary of the committee, not later than October 30.

OHIO

Centenary of Western Reserve Medical School—Western Reserve University School of Medicine, Cleveland, will observe the one hundredth anniversary of its founding, October 27, with a special program consisting of Drs. George H. Whipple, Rochester, N. Y., on "Blood Plasma Proteins Their Production, Function, Substitution and Replacement", Alan Gregg, New York, "The Matrix of Medicine," and Reginald Litz, Boston, "The Crimson Thread."

Physician Honored by General Assembly—Dr. Errett Le Fever, Gloucester, member of the house of representatives, was honored by the Ohio General Assembly on March 9, which had been proclaimed "Le Fever Day." The House unanimously adopted House Joint Resolution number 28, proposing to honor Dr. Le Fever on his twenty-first year of service in the legislature. The resolution states that Dr. Le Fever is the only man in the history of the general assembly to have served for twenty-one years. He first represented Athens County in the house of representatives in 1900-1901. He has since held the same position in 1904-1905, 1921-1922, 1933-1934, 1939-1940, 1941-1942 and the current session 1943-1944. He was also a member of the state senate during the years 1923 to 1930, representing the Ninth-Fourteenth districts. Dr. Le Fever graduated at the Medical College of Ohio, Cincinnati, in 1890.

OREGON

Personal—Dr. Donald J. Bourg, The Dalles, recently health officer of Wasco and Sherman counties, has been named to a similar position in Benton and Polk counties with offices in Corvallis. —Dr. Claude C. Chick has been named health officer of Hood River.

Sommer Memorial Lectures—Ernest Carroll Faust, Ph.D., professor of parasitology and head of the department of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans will deliver the third in a series of Ernest A. Sommer Memorial Lectures, May 17-22, at the University of Oregon Medical School, Portland, on the following subjects:

- Horizons of American Tropical Medicine, May 17
- Insects and Their Allies as Conduits Agents and Transmitters of Disease, May 18
- Malaria, May 19
- Yellow Fever and Dengue, May 20
- Anchuriasis and Related Infections of the Bowel, May 21
- Filariasis, May 22

New Dean at Oregon Medical School—Dr. David W. E. Baird Jr., acting dean, has been appointed dean of the University of Oregon Medical School, Portland, to succeed Dr. Richard B. Dillehunt, who resigned. Dr. Baird was born in Baker, Oct. 21, 1898. He graduated at the medical school in 1926. He was named assistant clinical professor in medicine in 1932 and in 1935 was named medical director of hospitals and clinics. He was appointed associate dean in 1938. Dr. Dillehunt, who graduated at Rush Medical College in 1910, has been associated with the Oregon faculty since 1912, first as professor of anatomy and assistant dean and later as clinical professor of orthopedic surgery and head of the department. He had been dean since 1920.

PENNSYLVANIA

License Revoked—The state board of medical education and licensure on March 26 revoked the license to practice medicine in Pennsylvania of Dr. John Herriott Boyd, Beaver town. The action was taken on evidence that Dr. Boyd was addicted to the use of narcotic drugs and alcohol to such an extent as to make him unfit for the practice of medicine, the board reported.

War Conference for Civilian Physicians—A combined meeting of the sixth and seventh councilor districts of the state medical society in Williamsport, May 14, constituted a war conference for civilian physicians. Among the speakers were Drs. Robert L. Anderson, Pittsburgh, on "Civilian Medical Practice in Wartime", Walter T. Donaldson, Pittsburgh, "War Participation and Organized Medicine," and Herbert J. Kelly, Philadelphia, "The Modern Science of Nutrition and Nutritional Deficiency." A feature of the meeting was the

presentation of fifty year testimonial certificates to Drs William J Campbell, Mount Union Isaac G Headings, McAlisterville Ella N Ritter, Williamsport Henry D Hart, Genesee, and Nathan W Church, Ulster

Philadelphia

Fifty Year Citations Awarded—At the ninety-first annual commencement of the Woman's Medical College of Pennsylvania, March 11, citations were awarded to the following fifty year graduates. Drs Jessie W Fisher Middletown Conn Charlotte E Goodman, Mount Pleasant, Pa, Katharine S Munhall, Buffalo Ella N Ritter Williamsport Pa, Martha P Sanborn, Kingston, N H, Rhys Wilson-Swan, Ankon Ohio Emma P Weeks Metzger Riverside N J Rachelle S Yarros La Jolla Calif, Ella M Anderson, M F McKirchian-Lions and Maria C Walsh

SOUTH CAROLINA

State Medical Election—Dr William R Wallace Chester was chosen president-elect of the South Carolina Medical Association at the annual meeting of the house of delegates recently and Dr William Atmar Smith Charleston was inducted into the presidency. Dr Arthur P McElroy Union was elected vice president and Dr Julian P Price, Florence, was reelected secretary-treasurer

WASHINGTON

Resigns as State Medical Adviser—Dr William E Steele, Olympia has resigned as chief medical adviser to the state department of labor and industries to engage in private practice in Seattle. Dr Steele, who held the state position for seven years, will be named consultant to the department in the Seattle area newspapers reported April 8

WEST VIRGINIA

Physicians Needed—The Merit System Council of West Virginia announces unassembled examinations for positions in the state health department and state department of public assistance. Applications will be accepted continuously but new registers will be established from applicants that file no later than June 26. Positions for which applications are being accepted and their respective salary ranges are listed herewith. Appointments may be made at above the minimum salaries

Director of maternal and child hygiene	\$4 200	\$4 800
Assistant director maternal and child hygiene	3 840	4 500
Director industrial hygiene	4 200	4 800
Director vital statistics	4 200	4 800
Director communicable diseases	4 200	4 800
Assistant director of communicable diseases (tuberculosis)	3 840	4 500
Assistant director of communicable diseases (venereal diseases)	3 840	4 500
Venereal disease consultant	3 840	4 500
Director Bureau of Dental Hygiene	3 840	4 500
Director of county health work	4 200	4 800
Senior health officer	3 840	4 500
Junior health officer	3 360	3 840
Health officer trainee	2 400	
Assistant director Hygienic Laboratory	2 640	3 240
Senior bacteriologist	1 800	2 400
Senior serologist	1 800	2 400
Consultant nurse in special fields	2 400	3 000
Public health nursing supervisor (state)	1 920	2 400
Public health nursing supervisor (local)	1 800	2 040
Chief of medical services	4 800	5 280

WISCONSIN

Lectures on Tropical Medicine—Dr Harold William Brown, dean of the University of North Carolina School of Public Health Chapel Hill N C lectured at the University of Wisconsin Medical School Madison April 28 under the auspices of the National Research Council. His subjects were Malaria and Parasitic Infections

Typical Home Front Physician Chosen—Dr Harry A Keenan Stoughton, has been selected by *Look* as the typical home front physician in wartime. As the choice of the magazine he represents the group on whom the community depends for protection and guidance in health and whose great burden is to double its work in order to relieve younger doctors for military service

Safety Conference—The sixteenth annual Rock River Valley Safety Conference will be held at the Hotel Rogers Beaver Dam May 16. Consideration will be given to women in industry absenteeism eye conditions of interest to industrial nurses employee training as it relates to accident prevention investigation of accidents for cause accident prevention in connection with women in industry safety programs for a county highway department dust explosion hazards and dangerous dusts

GENERAL

Warning on Fletcher's Castoria—The Centaur Company, Rahway, N J manufacturers of Fletcher's Castoria, in cooperation with the U S Food and Drug Administration on May 5 issued a national warning to all holders of Fletcher's Castoria to discontinue its sale and use because of the discovery that all such Castoria shipped since March 1, 1943 contains a foreign ingredient which causes nausea and vomiting. As neither consumers nor retailers can tell the difference between the packages made before March 1 and those produced thereafter, it is necessary to withdraw and recover all Fletcher's Castoria outstanding. All stocks should be returned to the manufacturer for a refund

Examinations in Internal Medicine—The American Board of Internal Medicine will hold regional oral examinations in Philadelphia on May 26-29, Chicago on June 9-11 and New Orleans and San Francisco on dates to be announced later. Oral examinations in the subspecialties will be given at the same time and place. The written examination of the board will be held on October 18. Applications for admission to this examination must reach Dr William A Werrell assistant secretary-treasurer, American Board of Internal Medicine 1301 University Avenue, Madison, Wis, before September 1. Exceptions will be made in the cases of candidates in the armed forces. Candidates desiring consideration in the subspecialties should file their application at the same time

Nicholas Appert Medal Awarded to Dr Prescott—The Nicholas Appert Medal of the Chicago Section, Institute of Food Technologists has been awarded to Samuel Cate Prescott, Sc D, Brookline Mass emeritus dean School of Science, Massachusetts Institute of Technology. Announcement of the award was made at the April 20 meeting of the Chicago Section and presentation will be made at the annual banquet session of the Institute of Food Technologists at the Statler Hotel, St Louis June 3. Eligibility for the award, established in 1941 is based on preeminence in the field of food technology and on contributions to the progressive development of food manufacture and processing. Dr Prescott received his honorary degree from Bates College Lewiston, Maine, in 1923

Free Supplement to U S P XII—Owners of all copies of the U S P XII should fill in and mail the post card order which is tipped inside the back cover of the U S P XII entitling the holder to a copy of the first U S P XII bound supplement soon to be issued. It was not expected that this supplement would be issued until about two and one-half years after the appearance of the U S P XII but changing conditions and wartime demands have necessitated its immediate publication. The supplement itself will carry a similar order form for a second bound supplement should the latter be required before the appearance of the U S P XIII. It is expected that the first U S P XII bound supplement will be available within two months and when it becomes available immediate shipment will be made without further cost to those who mail in their order cards as directed

Handbook on Rheumatic Fever—Rheumatic Fever in Children—Its Recognition and Management' a thirty-two page clinical handbook for the practicing physician has just been released by the Metropolitan Life Insurance Company and is being made available to physicians without charge chiefly through the 16 000 field representatives of the company. Physicians who wish a copy and who have not secured one by June 1 should write to Dr George M Wheatley New York assistant medical director Metropolitan Life Insurance Company 1 Madison Avenue New York. The book assembles the modern concepts of the disease its nature diagnosis and prognosis and the individual and community problems involved in the care of the patient. A group of clinicians in the following organizations assisted in the preparation of the book. American Heart Association American Academy of Pediatrics Children's Bureau of the U S Department of Labor and the U S Public Health Service. Other educational material has been developed by the Metropolitan Company in connection with its national program to reach the general public and the medical profession with information on rheumatic fever

CORRECTION

Wilson G Smilie—In his discussion on page 8 of *THE JOURNAL* of May 1 Dr Wilson G Smilie's first name was erroneously printed as Watson also in the ninth line in the second paragraph of Dr Smilie's discussion on this page the number of students should have been 3000 instead of 30000

April 3, 1943

The British Medical Association and the Beveridge Scheme

The meeting of the representative body of the British Medical Association to consider the national medical service proposed in the Beveridge scheme has taken place and the following resolutions have been adopted: 1 That the government's invitation to enter into discussions without commitment be adopted. 2 That a committee representative of the profession as a whole should in response to the government's invitation now enter into discussions with representatives of the minister of health on "a scheme for comprehensive health and rehabilitation services for the prevention and cure of disease and restoration of capacity for work available to all members of the community" (assumption B of the Beveridge report) in the light of the following undertakings now given:

1 That at the conclusion of the discussions and at the appropriate time during the discussions, but in any case before negotiations open and before any proposals are submitted to Parliament, the full machinery of the association including the council and its committees, groups, panel committees, divisions and the representative body, will be used to consider the government's proposals and to decide the association's view thereon.

2 That every practicable step will be taken to give all members of the profession, whether members or nonmembers of the association, an opportunity to express their views, and in particular that every practicable step will be taken to give members of the profession in war service an opportunity of expressing their views, to assess those views and to present them to the meeting or meetings of the representative body called to consider any proposals of the government.

The Employment of the Blind and Deaf

The total number of blind persons in Britain in 1941 was approximately 83,000, of whom about 42,000 were under 16 or over 65 years of age. Of the remainder about 9,000 are in employment. Some are employed in a selected group of ordinary industrial processes such as chocolate packing and testing precision instruments, in which delicacy of touch compensates for blindness. Others are employed in occupations regarded as specially suited to blind persons, such as telephonists, typists, masseurs and piano tuners, or in occupations such as basket and mattress making, which they have learned in blind training institutions. The majority—over 6,000—are employed in blind workshops or under home workers schemes. Of the remaining 32,000 in the 16-65 age group a considerable number have mental and physical defects which make them unemployable. Some do not need to work, such as the blind wives of sighted husbands, and a small proportion are receiving training in institutions.

The education and training of the blind is the duty of the local education authorities, and responsibility for their subsequent welfare is the duty of the local health authorities. These have no obligation to provide employment of a specific character, but nearly all have arranged, generally through a local voluntary association, for employment in workshops for the blind or in work at home. The Committee on the Rehabilitation and Resettlement of Disabled Persons considers that the local education authorities should have the obligation to provide vocational training.

Those blinded in war service are in the special charge of St Dunstons, an institution established for the purpose after the first world war. This provides treatment on behalf of the Ministry of Pensions and subsequently undertakes full vocational training and assistance in obtaining employment.

Employment of the deaf is a much more limited problem. Local education authorities provide suitable education up to the age of 16 for all children too deaf to be taught in a hearing class and vocational training thereafter. On leaving school at 16 the large majority of deaf children have already received manual or practical instruction to assist them to obtain remunerative employment. In general, deafness is a bar to employment only in certain occupations.

The Electroencephalogram as Evidence Against Criminal Responsibility

The first use of the electroencephalogram in a criminal case as evidence on the question of responsibility was reported in a previous letter (*THE JOURNAL*, January 2, p. 64). It has just been used a second time. A student aged 20 was charged with the murder of his mother, who was an American, in her London flat. Two physicians gave evidence on his behalf. They knew that before he killed his mother he had drunk 4 pints of beer. They gave him this quantity of mild beer and found that his sugar content was lowered. Tested with the electroencephalograph, the impulses from his brain were found to be erratic and definitely abnormal when his blood sugar was reduced. Charts of these tests were studied by the jury when they retired to consider their verdict. They found him guilty of murder but insane when he killed his mother. He was therefore sentenced "to be detained during the king's pleasure," which means that he will be detained as long as his mental condition is considered dangerous.

Mr Justice Asquith explained to the jury the celebrated McNaghten rules, which have just reached their centenary. They were laid down by judges in answer to questions put to them in the House of Lords after debates. They lay down that to establish the plea of insanity in a criminal case it must be proved that at the time of the offense the accused was laboring under such a defect of reason as not to know the nature and quality of his act or, if he did know it, he did not know that he was doing wrong. The medical witnesses in the present case agreed that the prisoner was abnormal, but they also said that when he killed his mother he knew what he was doing and knew that he was doing wrong. Mr Justice Asquith therefore could not advise the jury that the McNaghten rules applied, thus summing up in favor of a verdict of murder simply. The jury would not follow the judge's advice, which they had a perfect right to reject. They were evidently influenced by the abnormal electroencephalograms produced at the trial.

Birth Rate for 1942 the Highest for Fourteen Years

The quarterly return of the registrar general for England and Wales, just published, shows that the total live births for the last quarter of 1942 were 160,679, the highest for any fourth quarter since 1926. For the whole of 1942 the number was 655,075, nearly 68,000 more than in 1941 and the highest since 1928. The rate per thousand of population was 15.8, which was 1.6 higher than in 1941 and the highest since 1931, when the rate was the same. Live births exceed total deaths (both civilian and noncivilian) by 175,168, compared with 52,048 in 1941 and an average of 99,585 for the five years 1936-1940. The improved vital statistics, during the war as well as the diminution of disease, excepting venereal diseases, tuberculosis and cerebrospinal meningitis, which are always increased, have been pointed out in previous letters.

Deaths

William Gustav Exton ☉ New York, Columbia University College of Physicians and Surgeons, New York, 1896, member of the American Public Health Association, American Urological Association, Association of Life Insurance Medical Directors, American Association for the Advancement of Science and the American Chemical Society, member and past president of the American Society of Clinical Pathologists, in 1914 became director of the laboratory of the Prudential Life Insurance Company in Newark, N. J., and three years later planned and began the direction of the company's longevity service, an inventor of many diagnostic devices, among them the gastroscope, turbidimeter, euscope, spectroscopic method of colorimetry, scopometer and photoelectric scopometer, in 1933 devised a method for measuring the number, diameters, volume and hemoglobin content of red blood cells, the recipient of the Burdick Memorial Medal of the American Society of Clinical Pathologists, served on the staffs of the Sydenham Hospital, St. Joseph's Hospital and the Mount Sinai Hospital, where he died, March 12, of pneumonia, aged 67.

W. Holbrook Lowell ☉ Boston, Harvard Medical School, Boston, 1902, specialist certified by the American Board of Ophthalmology, member of the American Ophthalmological Society and the New England Ophthalmological Society, an associate in ophthalmology at the Harvard Medical School, Courses for Graduates, consulting surgical ophthalmologist to the Massachusetts Eye and Ear Infirmary, Boston, the Lawrence Memorial Hospital, Medford, Lawrence (Mass.) General Hospital, Massachusetts General Hospital and the Winchester (Mass.) General Hospital, member of the medical advisory committee of district number 34 of Massachusetts during World War I, aged 67, died, March 31, at his home in Winchester of coronary heart disease.

Joseph Dean, Madison, Wis., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, specialist certified by the American Board of Surgery, fellow of the American College of Surgeons, member and past president of the state board of health, from 1905 to 1921 associated with the Madison General Hospital one of the chief sponsors in the building of St. Mary's Hospital, where he was a member of the staff, a bronze plaque bearing his name was erected over the entryway of the hospital, in 1929 he and his brother founded the clinic which bears their name, aged 64, died, March 5, of coronary heart disease.

Adelbert Franklin Williams, Phippsburg, Maine, Dartmouth Medical School, Hanover, N. H., 1897, past president of the Sagadahoc County Medical Society, served in France as a captain in the medical corps of the U. S. Army during World War I, major in the medical reserve corps of the U. S. Army not on active duty was associated with the U. S. Veterans Bureau in Portland and the Veterans Administration facilities in Augusta and Togus, for ten years chief medical officer at the Portland regional office, aged 72, on the staff of the Bath (Maine) Memorial Hospital, where he died, March 11, of cerebral hemorrhage.

Charles Frederick McComb ☉ Duluth, Minn., Rush Medical College, Chicago, 1879, an Affiliate Fellow of the American Medical Association and member of the House of Delegates in 1909, 1910 and 1911, for many years coroner of St. Louis County, past president of the Minnesota State Medical Association, the first president of the Interurban Academy of Medicine, twice president and once vice president of the St. Louis County Medical Society, formerly member of the state board of health, served during World War I, aged 85, died, March 3, of pneumonia and arteriosclerotic heart disease.

Lloyd Leroy Krebs ☉ Major, U. S. Army, retired, Sierra Madre, Calif., University of Pennsylvania Department of Medicine Philadelphia, 1899, Army Medical School in 1902, entered the U. S. Army as an assistant surgeon in 1901 and was honorably discharged as a captain in 1911, was retired as a major in the medical corps of the U. S. Army in 1912 under a special act of Congress approved in the same year for many years a member of the staff of the Collis P. and Howard Huntington Memorial Hospital Pasadena, aged 68, died recently in Pasadena of myocardial infarction and coronary thrombosis.

Paul Virgil Winslow, New York, Albany Medical College 1908, member of the Medical Society of the State of New York, formerly sanitary supervisor of Dutchess, Greene and Columbia counties for the New York State Health Department, instructor in larvngology at the New York Medical School and Hospital 1920-1921, at one time on the staffs of the Hudson River State Hospital Poughkeepsie, and the

Brooklyn State Hospital, examining physician at the Army Induction Station, aged 57, died, March 12, in the Flower and Fifth Avenue Hospitals of lobar pneumonia.

C. M. Anderson, Jonestown, Miss., Memphis (Tenn.) Hospital Medical College, 1903, member of the Mississippi State Medical Association, aged 62, died, March 16, in the Baptist Memorial Hospital, Memphis, of uremia.

Charles Victor Barley, Ithaca, N. Y., Stanford University School of Medicine, San Francisco, 1928, member of the American Academy of Pediatrics, assistant attending physician, Cornell University Infirmary and Clinic, aged 41, died, March 3, of dissecting aneurysm and coronary occlusion.

Royal August Becker, Atlantic, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1910, member of the Iowa State Medical Society, served during World War I, on the staff of the Atlantic Hospital, aged 56, died, March 6, of congestive heart disease.

John Henry Belyea, Los Molinos, Calif., St. Louis College of Physicians and Surgeons, 1889, member of the California Medical Association, aged 78, died, March 6, in St. Elizabeth's Mercy Hospital, Red Bluff, of cerebral hemorrhage and arteriosclerosis.

Harry Walrod Blair, Mount Vernon, Ohio, University of Wooster Medical Department, Cleveland, 1892, member of the Ohio State Medical Association, served as a captain in the medical corps of the U. S. Army during World War I, for many years health officer, aged 77, died, February 19, of cerebral hemorrhage.

William C. Bovard, Apollo, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1878, aged 91, died, March 1, in the Citizens General Hospital, New Kensington, of coronary thrombosis.

John Clinton Boyer, Ocean City, N. J., Jefferson Medical College of Philadelphia, 1898, aged 70, died, March 12, of cerebral hemorrhage and arteriosclerosis.

Walter Miles Browning, Waurika, Okla., Memphis (Tenn.) Hospital Medical College, 1897, member of the Oklahoma State Medical Association, formerly a druggist, aged 73, died, February 5, in the Medical Arts Hospital, Dallas, Texas.

Francis E. Butler ☉ Menomonee, Wis., Milwaukee Medical College, 1903, president of the State Medical Society of Wisconsin and formerly counselor of the Tenth District, past president of the Dunn-Pepin Counties Medical Society, fellow of the American College of Surgeons, founded the Menomonee Clinic, on the staff of the Menomonee City Hospital, a member of the Menomonee Chamber of Commerce, the Rotary Club and the city council, aged 62, died, March 12, of carcinoma of the prostate.

Fred Allen Cobb, Toledo, Ohio, Toledo Medical College, 1894, member of the Ohio State Medical Association, formerly city councilman, served during World War I, aged 77, member of the emeritus staff of the Robinwood Hospital, where he died, March 9, of a fracture of the hip from a fall and paralysis agitans.

Warren Hamilton Conner, Los Angeles, State University of Iowa College of Homeopathic Medicine, Iowa City, 1893, aged 87, died, March 1.

Joseph Edgar Dibble, Kansas City, Mo., Meharry Medical College, Nashville, Tenn., 1895, veteran of the Spanish-American War, first lieutenant in the medical reserve corps of the U. S. Army not on active duty, on the staffs of the Wheatley-Provident Hospital and the Kansas City General Hospital, number 2, surgeon for the Kansas City Southern Railroad, aged 69, died, March 9, of cerebral hemorrhage and vascular hypertension.

Frank Newcomer Emmert, Chambersburg, Pa., Bellevue Hospital Medical College New York, 1898, member and at one time vice president of the Medical Society of the State of Pennsylvania, past president of the Franklin County Medical Society, treasurer for many years and on the staff of the Chambersburg Hospital, aged 69, died, March 15, in Jacksonville, Fla.

Hicks C. Fenton, Portland, Ore., University of Oregon Medical School Portland, 1893, aged 74, on the staff of St. Vincent's Hospital where he died February 6 of coronary occlusion.

Royce Day Fry, Euclid, Ohio, Western Reserve University Medical Department Cleveland 1883, veteran of the Spanish-American War, aged 87, died February 21.

William H. Funkhouser, Evansville Ind., Louisville (Ky.) Medical College 1882, aged 85, died February 7, in an Indianapolis hospital.

William W. Greenwood, Navasota, Texas, University of Texas School of Medicine, Galveston 1899, member of the State Medical Association of Texas, health officer of Navasota, served as president of the school board and as local surgeon for the Southern Pacific and Missouri Pacific railroads, aged 68, on the staff of the Brazos Valley Sanatorium where he died, March 2, of meningitis.

Maurice William Gumpert, Huntington Park, Calif., University of California Medical School San Francisco 1930, member of the California Medical Association, aged 42, died, February 24, in Los Angeles of carcinoma of the stomach.

Edwin Arnold Hyatt * St. Albans, Vt., McGill University Faculty of Medicine Montreal Que. Canada 1902, past president of the Vermont State Medical Society, member of the staff of St. Albans Hospital, aged 67, died, February 11.

Thurlock Milton Jewell, Milford, Iowa, Northwestern University Medical School, Chicago, 1929, aged 38, died, February 14, in Spencer of bronchopneumonia.

Emil E. Johnson * Cortez, Colo., Chicago College of Medicine and Surgery, 1912, past president of the San Juan Medical Society, formerly owner and superintendent of a hospital bearing his name, served as alderman, mayor, county physician and health officer for many years, aged 61, died, February 15, in Santa Monica, Calif., of coronary thrombosis.

Paul Vincent Joyce * Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1912, served as a lieutenant in the medical corps of the U. S. Army during World War I, formerly a police surgeon, on the staffs of the Wesley Memorial Hospital, St. Anthony's Hospital and the Washington Boulevard Hospital, now closed, aged 59, died, April 30.

Frederick Anton Keller, Falls City, Neb., Emsworth Medical College, St. Joseph, Mo., 1902, aged 61, died, March 3, of diabetic gangrene.

Edward Martin Lawler, Cudahy, Wis., Marquette University School of Medicine, Milwaukee 1932, member of the State Medical Society of Wisconsin, aged 36, died suddenly, February 27, of coronary thrombosis.

Louis Loveman Lefkowitz * New York, University and Bellevue Hospital Medical College, New York, 1921, specialist certified by the American Board of Pathology, Inc., served as assistant professor of pathology at the New York University Dental School, was president of the Bronx Pathological Society, an assistant medical examiner of the Bronx, on the staffs of the Bronx and Montefiore hospitals, aged 44, died, March 6, of coronary thrombosis.

Gustav Herman Luedtke * Fairmont, Minn., University of Minnesota College of Medicine and Surgery, Minneapolis, 1899, for many years health officer of Fairmont, served as a major in the medical corps of the U. S. Army during World War I, on the staffs of the Fairmont Community and Hunt hospitals, aged 72, died, March 18, of carcinoma of the prostate.

J. Carroll Montgomery, Topeka, Kan., College of Physicians and Surgeons, Medical Department Kansas City University, Kansas City, 1901, formerly associated with the U. S. Public Health Service, at one time health officer of Sedgwick County and Cherokee County, formerly director of child hygiene and rural sanitation, Kansas State Board of Health, served as secretary of the Kansas Public Health Officers' Association, aged 68, died, February 2, of cerebral arteriosclerosis.

Hugh Lewers Murphy, Arkabutla, Miss., Louisville (Ky.) Medical College, 1905, member of the Mississippi State Medical Association, aged 60, died, February 20, in the City Hospital, Indianapolis, of cerebral hemorrhage.

Nathaniel Otis Owens, Quincy, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1897, member of the Missouri State Medical Association, aged 69, died, March 2, of heart disease.

William Bradley Palmer, Furman, Ala., Medical Department of Tulane University of Louisiana, New Orleans, 1898, aged 75, died, March 1, in a hospital at Atlanta, Ga., of coronary occlusion with rupture of the left ventricle, malignant nephrosclerosis and arteriosclerosis.

Halfdan Raasoch, Nelsonville, Wis., Rush Medical College, Chicago, 1896, for seventeen years school clerk, village president and for many years health officer, aged 70, died, February 19, of angina pectoris.

Roland Ray Reed * McCook, Neb., University of Nebraska College of Medicine, Omaha, 1910, served overseas with Field Hospital unit number 40 during World War I, aged 56, died, February 13, of coronary disease.

Martin Abraham Reichman, Morrisonville, Ill., University of Illinois College of Medicine, Chicago, 1929, member of the Illinois State Medical Society, served as a member of the local board of health, aged 38, died, February 27.

Charles Freelan Rosenberg, Milwaukee, University of Wisconsin Medical School, Madison, 1936, at one time a member of the staff of the Normandale, Madison, aged 33, died, February 27, in the Columbia Hospital of coronary thrombosis, secondary to emboli from osteomyelitis.

Frank Louis Sharpe, Statesville, N. C., University of North Carolina School of Medicine, Chapel Hill, 1904, member of the Medical Society of the State of North Carolina, aged 74, died, February 20.

Oliver O. Simpson, Norcross, Ga., Atlanta Medical College, 1882, formerly member of the state legislature, county commissioner of Gwinnett County and mayor of Norcross, aged 85, died, March 4, in the Emory University (Ga.) Hospital of thrombosis.

Douglas Bins Staggs, Monmouth, Iowa, Hahnemann Medical College and Hospital, Chicago, 1896, aged 71, died, February 13, in Anamosa of acute general peritonitis.

Tully A. Summers, Nevada, Texas, University of Tennessee Medical Department, Nashville, 1894, formerly on the staff of St. Paul's Hospital, Dallas, aged 70, died, February 27, of angina pectoris.

Carl Whit Sutton * Richlands, N. C., Medical Department of Tulane University of Louisiana, New Orleans, 1905, aged 60, died, February 20, in the Memorial General Hospital, Kingston of cirrhosis of the liver.

Routon Beverly Taylor, Jena, La., College of Physicians and Surgeons, Little Rock 1911, aged 69, died recently at the Vaughan-Wright-Bendel Clinic, Monroe.

Willis Stinson Taylor, Columbus, Ohio, Eclectic Medical Institute, Cincinnati, 1885, for many years associated with the board of health of Franklin County, aged 83, died, February 14, in the Grant Hospital of thrombosis.

W. T. White, Ratchiff, Ark. (licensed in Arkansas in 1903), aged 60, died recently.

Allen Bishop Wilson, Hagerstown, Md., Leonard Medical School, Raleigh, N. C., 1902, aged 66, died, February 20, of pulmonary tuberculosis.

Frank Le Roy Young, Knoxville, Tenn., University and Bellevue Hospital Medical College, New York, 1906, member of the Tennessee State Medical Association, at one time professor of otology, laryngology and rhinology at the Lincoln Memorial University Medical Department, aged 63, died, February 18.

Claude Youtsey, Newport, Ky., Medical College of Ohio, Cincinnati 1903, member of the Kentucky State Medical Association, past president of the Campbell County Medical Society, served as president of the Campbell County Board of Health and for many years as a member of the board of health of Newport, chief of the medical staff and vice president of the board of directors of Speer's Memorial Hospital, Dayton, medical examiner for the Selective Service Board number 21, aged 61, died, March 5, of carcinoma of the right lung.

DIED WHILE IN MILITARY SERVICE

Lewis Edward Barrick, Chicago, Northwestern University Medical School, Chicago, 1940, first lieutenant in the medical corps of the Army of the United States, aged 29, died, January 9, in Denmark, Iowa, of injuries received in an airplane accident.

Jay Henry Caldwell, Long Beach, Calif., College of Medical Evangelists, Los Angeles, 1941, first lieutenant in the medical corps, Army of the United States, aged 33, died, February 27, in an airplane accident at Santa Ana.

John Morgan Clack, West Point, Ga., University of Tennessee College of Medicine, Memphis, 1929, member of the Medical Association of the State of Alabama, past president of the Chambers County (Ala.) Medical Society, first lieutenant in the medical corps of the Army of the United States, aged 37, died, January 30, in Edmonton, Canada, of a coronary thrombosis.

John Patrick Gavan, Cleveland, St. Louis University School of Medicine, 1929, a member of the staff of St. John's Hospital, captain in the medical corps of the United States Army Air Corps, aged 40, died, February 22, at Mitchel Field, Long Island, N. Y., of pneumonia.

THE PHYSICAL FITNESS PROGRAM

To the Editor —It was my privilege recently to visit one of the Navy preflight schools in which the emphasis is on indoctrination, certain phases of technical training, and physical fitness. At this school they have, in addition to the regular Navy line officers and a specially commissioned staff of physical education and athletic leaders, a remarkably fine medical and dental staff organization. These physicians and dentists are doing a splendid job in examination, surgery care of injuries and illness, and guidance, as far as excuse from regular activity and class work for medical reasons is concerned. Infirmary and hospital facilities of an outstanding type are available and are being well used. In addition to the usual entrance medical examination this medical group is administering a mass X-ray examination of the lungs by use of a 35 mm film unit.

The program at this preflight school at one time involved approximately six hours of physical training per day. This has now been reduced to the equivalent of three hours of physical training a day, for various reasons. The usual physical training period for the Army and Navy, I am told, is one hour per day at the earlier and later aviation training stages.

The end results of this program have been evaluated in terms of physical measurements, speed and exercise tests based on pulse response to a modification of the step test. This testing program is conducted by the physical education phase of the school. The objective testing demonstrates average improvement in the physical speed and improved exercise response, and anthropometric measurements.

The medical group is doing a magnificent job, but it should be pointed out to the general medical profession in this country that, while the physical education group at the school is testing for objective results of this most intensive physical training program in history in America, the medical group and dental group at this station are limited pretty much to a clinical and empirical opinion as to the evaluation of what might be called medical results of the program. At certain advanced naval aviation training schools a research medical program is being administered.

It appeared to me that, with this tremendously intensive program of physical strain, medicine is overlooking a great opportunity for the obtaining of scientific knowledge of the medical results of intensive physical activity such as is being administered in this first experiment in American history. The medical officers themselves seem interested in such an opportunity, for example a more comprehensive entrance examination with an opportunity for a similar comprehensive follow-up examination at the end of the program under controlled conditions. Under present circumstances the staff is so limited, as is the very outstanding staff of the adjacent medical college that such follow up does not seem practical because as several stated, This is war.

Under the conditions of a great opportunity to do further investigation as to the results of intensive exercise on a level never before seen and a marvelous medical setup in a great medical center it remains for the Navy to allow the medical follow up program or for the physical fitness committee of the American Medical Association to set up and subsidize such a program, if the consent of the Navy could be obtained. It is such a wonderful opportunity to get facts heretofore not avail-

able that I urge its importance on the officials and the appropriate committee of the American Medical Association.

The research work now being done, for example in cardiology on the advanced flying basis, is magnificent, but this work is not being done on a group of potential aviators who are undergoing an intensive physical education activity program such as that which is being administered in the preflight schools. Statistics on the reasons for morbidity and "wash out" (academic and medical) are not fully available at the various preflight schools. The results of this intensive program cannot be said to be as yet scientifically evaluated. Such evaluation is a medical challenge, a physical education challenge, and I suggest the extreme desirability of the medical group attempting to make possible such investigation, so that future programs and the inevitable after war physical fitness program may be more intelligently, scientifically and less empirically approached.

I trust that this suggestion may not be misunderstood by anybody, as I believe a magnificent piece of work is being done by these preflight schools in toughening and training future naval aviators. My only point is that we cannot know scientifically what the end result of such intensive training may be, especially for certain men who enter training without having been particularly athletic, and such investigation would seem to be tremendously significant, particularly in respect to the possible cardiac, pulmonary, renal and neuropsychiatric effects as well as in its more obvious traumatic aspects.

Director University Health Service,
Ohio State University

THERAPY OF SEVERE BURNS

To the Editor —An editorial comment (THE JOURNAL April 3 p 1157) on the 'Therapy of Severe Burns' calls attention to the report of Elman, Cox, Lischer and Mueller (*Proc Soc Exper Biol & Med* 51:350 [Dec] 1942). These authors working with experimental burns in rats demonstrated that the acute mortality was greatly elevated in animals kept at environmental temperatures of 32, 55 and 99 F as compared with groups of rats kept at 75 F.

May I call your attention to the fact that I have reported similar results in mice in an article entitled 'Experimental Chemotherapy of Burns and Shock. I. Methods. II. Effects of Local Therapy on Mortality from Shock' (*Pub Health Rep* 57:1923 [Dec 18] 1942) which appeared simultaneously with the publication cited. Mention should also be made of the recent article of Wakim and Gatch 'Effects of Temperature on Shock' which appeared in THE JOURNAL March 20 page 905. They came to essentially the same conclusions as to the harmful effects of heat and cold in traumatic shock, as a result of their experiments on several species of animals.

Because of their possible clinical significance may I also mention the results I have recently obtained in the treatment of burn shock in mice (*Pub Health Rep* 58:513 [March 26] 1943). Evidence was presented that the acute mortality following a standardized burn is primarily related to a sodium deficiency since death can be prevented by therapy with sodium salts by mouth and this effect can be antagonized by potassium salts. Intravenous therapy was less effective than other routes of administration.

SAMUEL M. ROSENTHAL, M.D., Bethesda, Md.
Principal Pharmacologist U. S. Public Health Service

METHOD OF ADMINISTERING PENTOTHAL SODIUM

To the Editor —In the March 6 issue of THE JOURNAL, Capt Robert B Hope described a holder for the administration of pentothal sodium. We have at our institution a much simpler method which places the anesthetist at the head of the table where he believes so that he may administer oxygen and further observe the patient. The accompanying diagram tells the nature of the method. There is about 3 feet of narrow gauge tubing that fits on the end of a 20 cc syringe and has an adapter at the other end to take a 22 long needle. This is inserted in the vein and secured there with adhesive tape as noted. The tubing is pinched off when the injection is not being made with an old Kelly clamp, so that there is no backflow of blood into the needle tubing and syringe. The tubing holds about 3 cc of pentothal. With this arrangement we have done all types of operations and it has been uniformly satisfactory. For wartime use if there is a shortage of hands one could have a nurse

Details of method

or orderly at the head of the patient and the doctor could assist the operator in an emergency and still give the anesthetic if the tubing and the syringe with the pentothal was sterile and could be brought into the field. This method has been used in over five hundred operations and I pass it along with the hope that some one may want to use the technique.

"THE GOOD SURGEON"

To the Editor —A number of friends have called my attention to a quotation attributed to Dr John M T Finney which appeared on page 1312 of the Dec 19, 1942 issue of THE JOURNAL.

The quotation was taken from an editorial in the August 1918 issue of *War Medicine*, it was written by Dr George Crile but not signed. Later the material was used in an address read by Dr Crile before the American Surgical Association on June 16, 1919. Instead of the original title, "The Good Surgeon: The Most Important Factor in the Treatment of War Wounds," the heading was "The Most Important Factor in the Treatment

of War Wounds and the Most Important Factor in Civilian Surgery—the Good Surgeon." This was published in the *Annals of Surgery* in October 1919, the article being almost identical with the editorial in *War Medicine*. It also appeared in the Transactions of the Association.

I was much interested in this recent reference to an article written during the first world war and feel sure you will want to correct your statement regarding the authorship.

TREATMENT OF CEREBROSPINAL MENINGITIS

To the Editor —The editorial "Treatment of Cerebrospinal Fever" (THE JOURNAL, February 13, p 516) may create an erroneous impression as regards the mortality from the disease in this country. For instance, since Jan 1, 1937 all epidemic meningitis patients admitted to the Division of Contagious Diseases, City Hospital, Cleveland, have been treated according to the method described by Hoyne, i.e. with a continuous intravenous drip of meningococcus antitoxin and at the same time massive doses of sulfanilamide by mouth, if possible. Lumbar punctures were made only for diagnosis. In 75 consecutive cases there were five deaths—a gross mortality rate of 6 2/3 per cent, only 1 patient had a complication—loss of hearing. Among 5 who succumbed was 1 who died fifty-five minutes after admission and a 50 year old woman with diabetes and gangrene who had recovered from the spinal meningitis and whose spinal fluid, at the time of death from other causes, contained only 69 cells. If we exclude these patients the mortality rate would be 4.1 per cent. Of the remaining 3 persons 1 died nineteen and one half, 1 twenty and 1 twenty-eight hours after admission to the hospital.

EDIBILITY OF RABBITS USED FOR PREG- NANCY TESTS

To the Editor —The communication by Drs Weisman and Coates in THE JOURNAL, March 27, page 1109, starts with the unwarranted assumption that rabbits utilized for pregnancy (Friedman) tests are unsuitable for food and that therefore a less satisfactory test should be substituted.

If rabbits are apparently in good condition when killed in order to read the test, they are as edible as litter mates which are killed primarily for food. Various members of my staff have been eating test rabbits for years with no harmful effects. They are more sought after now than previously, because of meat rationing. The line forms on the right.

Why should such animals not be eaten? The urine which was injected into their veins came from human beings who passed all the urinary materials through the blood without any toxic effects, and the hormones which produced the ovarian changes are among the profession's modern panaceas.

Let's conserve our professional and nutritional resources by making the rabbits do double duty.

If you're not a Babbit,
You'll enjoy the rabbit
That entered into rest
To give a Friedman test
While it may seem funny,
You'll enjoy the bunny,
Who's done her double duty
For Victory and Beauty

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Power of Licensing Board to Reinstate Revoked License—Buonanno was licensed to practice medicine and surgery in West Virginia in 1927. In 1930, after notice and hearing the public health council, the state agency charged with the duty of examining and licensing applicants for licenses to practice medicine and surgery and with revoking or suspending licenses for causes stated in the medical practice act, revoked Buonanno's license on the ground of dishonorable conduct on his part in submitting to the council a fraudulent medical diploma in applying for the license he obtained. Buonanno did not appeal from the order of revocation. In March 1934 he applied to the council for reinstatement of the revoked license presenting a diploma purportedly issued to him by the Medical College of the University of Rio de Janeiro indicating the completion in that institution of a course of study in medicine and surgery. The council ascertained that the diploma was not genuine and denied the application. He made several other fruitless attempts to induce the council to reinstate his license. In January 1940 he petitioned the circuit court of Marion County, West Virginia, for a review of the action of the council. The trial court sustained the council's demurrer to the petition and dismissed the action. Buonanno took no appeal from the action of the court. In November 1941 he again applied to the council for reinstatement and was notified that the council would pass on the application at a meeting in March 1942. Thereon the West Virginia State Medical Association sought a writ of prohibition to prevent the council from considering further the restoration of Buonanno's revoked license. The association alleged that Buonanno was not legally qualified to practice medicine and surgery in West Virginia, that if he were permitted to practice it would tend to degrade the professional standards of its members and that the revocation of his license by the council had long since become final by reason of his failure to appeal from the order of revocation entered in 1930 and that the council had no jurisdiction to consider further the restoration of his license. Buonanno, on his own motion, was made a party to the proceedings and demurred to the petition for a writ of prohibition for the alleged reason that the council had the legal power, if it saw fit, to reinstate his revoked license and that the court was without jurisdiction to prohibit the council from doing so. The trial court overruled the demurrer and he appealed to the Supreme Court of Appeals of West Virginia.

The writ of prohibition, Buonanno contended on appeal, does not lie to control the action of a board, such as the council, having only administrative functions. True, said the court, if the public health council possesses only administrative powers, a writ of prohibition to control it in the exercise of those powers should not issue. But the council in addition to its purely administrative functions has and exercises quasi-judicial powers and jurisdiction with respect to the suspension and revocation of licenses. It is not a judicial tribunal but in its own sphere it may hear and evaluate the evidence on a contested matter and make a finding which is subject to review by courts. While there is no express provision in the medical practice act or elsewhere authorizing the council to reinstate a revoked license to practice medicine if it has that power as cognate to the powers of revocation and suspension that power and jurisdiction must necessarily be quasi-judicial. Since the council is a quasi-judicial body a writ of prohibition will lie to prevent it when acting in its quasi-judicial capacity from exceeding its legal authority. The trial court therefore had jurisdiction and if in fact the council is attempting to exceed its jurisdiction and lawful power in restoring Buonanno's license prohibition will lie to restrain the council from doing so.

The Supreme Court of Appeals then considered the right of the council under the circumstances present in this case to reinstate Buonanno's revoked license. After the revocation of

Buonanno's license, said the court, in 1930 by the council, the only course left to him was to present the necessary valid, qualifying certificate of graduation from an approved medical school and take a new examination or within thirty days after the entry of the order of revocation to perfect an appeal to the courts. Buonanno did not apply for a new examination but attempted repeatedly to induce the council to reinstate his license. He did not appeal to the courts from the order of revocation. In 1940 he instituted an action in the circuit court of Marion County to review the council's refusal to reinstate his revoked license, not to review the propriety of the order of revocation. The propriety of the order of revocation could not be reviewed by the courts unless the court proceedings were instituted within thirty days after the entry of the order of revocation. In the absence of a statutory provision otherwise specifically fixing the finality of an order of the council revoking a license we hold said the court that the statute limiting the time for an appeal determines that question and that an order becomes final for all purposes after the expiration of thirty days and cannot thereafter be set aside or vacated by the council. The order of revocation entered in 1930 is final for another reason. When the medical association instituted this proceeding more than eleven years had elapsed since the order revoking Buonanno's license was entered and the order had not been vacated, modified or successfully challenged during that time. There must be a finality to proceedings before the council. To hold otherwise would result in a state of uncertainty and confusion preventing the orderly performance of council duties. We believe that the lapse of time alone is sufficient to give the order of revocation finality and that the council is precluded from a reconsideration of its order especially in view of the proceedings instituted by Buonanno in the circuit court of Marion County for review and reversal of the council's refusal to reinstate the revoked license. We therefore hold that the license of Buonanno has been finally and completely revoked prior to commencement of this proceeding and that he now has the same status with respect to the practice of medicine and surgery as if a license had not been issued to him.

For the reasons stated the order of the lower court in effect prohibiting the council from considering the restoration of Buonanno's license was affirmed—*Hest Virginia State Medical Assn v. Public Health Council of Hest Virginia* 23 S. E. (2d) 609 (11-1-1942).

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fifteenth Annual Meeting, held in Chicago, Nov. 6 and 7, 1942

The President, DR. ARTHUR R. BARNES, Mayo Clinic, Rochester, Minn., Presiding

(Concluded from page 136)

Clinical Use of Papaverine in Coronary Heart Disease

DRS. LOUIS A. KATZ and STEPHEN R. EICK, Chicago. Papaverine, a non-habit forming opium alkaloid of the benzylisoquinoline group, has been used abroad in angina pectoris but has received practically no attention in this country for this condition. Experiments have shown that it is a powerful coronary vasodilator, and experiences in this laboratory have demonstrated that it can abolish ventricular fibrillation and premature ventricular systoles in the dog and can also act prophylactically to prevent their occurrence.

We have therefore investigated its action clinically on patients with angina pectoris and on those with premature systoles. Three groups of patients were studied. In the first group were 17 ambulatory patients with an established severe anginal syndrome given papaverine by mouth $1\frac{1}{2}$ grains (0.1 Gm.) four times a day alternately with control periods on placebo. These patients kept a diary and were closely followed over periods of from five to eleven months. The effect was judged by comparing frequency of anginal attacks, duration of each attack, number of blocks patient could walk without pain, and amount of glyceryl trinitrate used. Twelve showed definite improvement on papaverine, 3 were inconclusive and 2 were slightly improved.

In the second group, included among other arrhythmias, there were 12 patients with frequent premature systoles. The effect of intravenous papaverine 1 to $1\frac{1}{2}$ grains (0.06 to 0.1 Gm.) was followed. In all there was a definite reduction or abolition of the premature beats for two to ten minutes after the injection. In 1 case the use of a slow intravenous drip ($1\frac{1}{2}$ grains in 125 cc. of isotonic solution of sodium chloride) led, after 1 gram had been administered, to disappearance of the multiple ectopic beats for several hours.

In the third group, 5 patients with frequent premature systoles were hospitalized and the effects of periods under oral papaverine, $1\frac{1}{2}$ to 3 grams (0.1 to 0.2 Gm.) four to five times daily were tested and compared with control periods and with periods on quinidine. The premature systoles were counted three times a day (sometimes hourly) during the control and drug periods. In all cases papaverine had a definite effect in decreasing the frequency or in abolishing the premature systoles, and the effect was equivalent to that of quinidine.

It was concluded from these studies that papaverine is of value in the alleviation of pain in angina pectoris and in the eradication of premature systoles. There is no contraindication to its oral use and little to its use intravenously. Because of these two actions, and its definite sedative action, papaverine has a definite place in the treatment of chronic coronary disease complicated by anginal pain or premature systoles. In the latter it may be considered a measure which can be taken to lessen the risk of fatal ventricular fibrillation. It appears to carry none of the hazards of quinidine, since it does not depress the heart's contraction. When used orally it must be given in larger doses than those ordinarily employed.

DISCUSSION

DR. GEZA DE TAKATS, Chicago. Since 1936 my associates and I have been using papaverine in acute vascular accidents intravenously in much smaller doses than the authors have mentioned. It was only natural to try to follow intravenous doses with oral doses in patients with peripheral vascular disease. We used 1 gram of papaverine three times a day orally. I cannot remember the exact number of patients but it must have been 20 to 25. The majority have become uncomfortable on these doses. Perhaps the massive doses that the authors mentioned might have counteracted the effect of smaller doses. Our patients would get out of bed and wander around. One patient had intractable obstipation. I should like to ask what the longest period was during which the authors used papaverine and what the effects were on withdrawal.

DR EDWARD MASSIE, St. Louis I should like to ask if there were any other electrocardiographic effects of papaverine apart from its effect on the rhythm

DR PAUL NOTH, Detroit In view of all the difficulties in evaluating the subjective response to drug therapy in angina pectoris, would the tests performed before and during therapy, such as the measured amount of exercise required to induce an attack of angina pectoris or changes in the electrocardiogram following exercise, have any supplementary value in the present study?

DR L. N. KATZ, Chicago We did not have the unpleasant side effects mentioned by Dr de Takats when he used smaller doses. In some patients sweating did occur but was not too unpleasant. Constipation occasionally occurred but could be controlled readily with ordinary means. We were impressed with the absence of side effects. No withdrawal symptoms were encountered. It is true that many patients like the drug and asked for its continuation, but these requests were on the same basis as requests for digitalis and other drugs which the patients considered benefited them. When told that no more drug was available, they did not complain or show any symptoms of withdrawal. Similar reports have appeared previously in the literature. Papaverine, therefore, is not habit forming. We made no attempt to analyze the electrocardiographic changes induced by papaverine aside from its effect on the arrhythmias. Precordial pain is a symptom not necessarily related to any specific electrocardiographic alterations. An effect on pain need not parallel an effect on the electrocardiogram and vice versa, and we were interested in its action on anginal pain. There is no contraindication to the use of papaverine with or following digitalis. We have used papaverine after digitalis and we have also used it with quinidine. I know of no pharmacologic or clinical contraindications for such combined uses. We did not believe it worth while to study the effect of papaverine on exercise tolerance since in our hands the induction of anginal pain with exercise was found to be unreliable quantitatively. We felt that more information could be obtained from the reaction of the patient to his daily activity than from any set exercise test provided the data were cautiously interpreted.

Observations on Shock

DR L. N. KATZ, R. ASHER and DR SAMUEL PERLOW, Chicago We have been able to produce shock in dogs with fatal termination, by nearly complete venous occlusion of one hind limb. This offers a simple way of studying the course of shock and the utility of some of the proposed therapeutic agents to counteract it. In our control series of 18 dogs 16 died in shock in three and one-half to twenty-one hours following the venous occlusion. All showed a definite drop in blood pressure, a rise in hematocrit and an increase in the occluded limb size amounting to 23 to 69 per cent of the body weight. The extensive loss of fluid into the occluded leg is the primary mechanism of this type of shock.

The effect of the following drugs on this type of shock was noted: (a) desoxycorticosterone acetate, (b) adrenal cortex extract and (c) paredrine hydrobromide.

Eleven dogs were treated with desoxycorticosterone acetate for twenty-four hours preoperatively and twenty-four hours postoperatively. Eight of these 11 primed dogs survived. The blood pressure showed no appreciable changes, the hematocrit was high during the early postoperative hours but subsequently returned to normal levels; some dogs developing a hemodilution. Although the occluded limb became edematous its average increase was not as great as those of the control series.

In 9 other dogs 3 received desoxycorticosterone acetate beginning two hours after the occlusion and continued for twelve hours while the other six received desoxycorticosterone acetate ten minutes to two and one-half hours preoperatively and during the first twelve postoperative hours. Of this group 7 died in shock, 1 of pneumonia and only 1 survived. The postoperative picture was almost identical with the control group.

Adrenal cortex extract was administered to 12 dogs twelve hours preoperatively and during the first twelve postoperative hours. Of this series 6 survived, 5 died in shock and 1 of bronchopneumonia. Our results show that adrenal cortex extract tends to reduce the amount of fluid lost into the

occluded limb, an action more striking than that of desoxycorticosterone acetate alone.

Paredrine showed no beneficial effects when administered to a group of six dogs. The drug was given postoperatively only. All animals died in shock within eleven hours following the operation.

In a group of 13 dogs we attempted to prevent the fluid accumulation into the occluded limb by mechanical means. Following the operation a rigid plaster cast was applied to both lower limbs, the groin and the lower abdomen. This cast was removed thirty-six hours later. Eleven of these animals survived, 1 died in shock and 1 of bronchopneumonia. No hemodilution occurred, the blood pressure showed no significant changes and the occluded limb was not edematous. However, edema did develop gradually after removal of the cast but had no deleterious effect on the animals. The absence of shock in this group of dogs emphasizes the fact that local accumulation of fluid determines this state not so much by the amount of plasma fluid lost but rather by the rate at which it is lost. This simple method of preventing shock caused by fluid loss, has practical application both in civil and in military practice.

DISCUSSION

DR HEINRICH NECHELES, Chicago I wonder whether the assumption of the authors that collaterals form is correct, because a traumatized leg will swell up to the limits permitted by the bandage. I think the same pressure on capillaries exists when one permits the leg to swell until the skin would limit further swelling. I do not think collaterals would form under any one of these conditions. Would not some other mechanism, like thrombosis, explain the phenomenon?

DR GEZA DE TAKATS, Chicago Would it not be simpler to use a snug wide rubber bandage instead of a cast? Undoubtedly the leg swells a great deal and if one puts on a cast there might be necrosis. I wonder if the authors have made observations with an Esmarch bandage, also if they have made any observations on renal involvement and whether they believe the entire picture is due to a fluid loss or to toxic substances which produce a hepaticorenal syndrome.

DR L. N. KATZ, Chicago There was no question in our minds that collateral veins do develop. Otherwise there is no way of explaining the disappearance of edema in the leg with occluded veins in the animals that survived. We had contemplated the use of a rubber stocking instead of the cast for these dogs, but this would have been less convenient and we were primarily interested in the principle of preventing edema formation, which could readily be accomplished with a cast. We have not yet made observations on renal involvement in this form of shock. As to the action of toxic substances absorbed in the blood stream I do not know whether they are involved in inducing other forms of shock. However, it would appear that in shock produced by venous occlusion such toxic substances are apparently not involved nor are neurogenic stimuli. The role of toxic substances and neurogenic stimulation are still the subject of polemics just as they were in the last war and still may be after this war is over. All the evidence tends to show that oligemia and a decreased venous return to the heart leading to a slowing in the circulation to vital parts of the body is the important mechanism involved in shock. The secondary effects resulting from this should be intensively studied since they lead to the irreversibility of shock.

Production of Experimental Shock in Dogs by Use of Venous Tourniquets

DR CHARLES C. SCOTT and E. BROWN ROBBINS, BS Indianapolis By applying pneumatic venous tourniquets to both thighs of dogs swelling results accompanied by fall in blood pressure and reduction of blood volume. The shock which subsequently develops has the following characteristics: (1) It is irreversible without transfusion therapy. (2) The degree of shock in each animal can be adjusted at will. (3) Hemorrhage and infection are eliminated as factors and (4) complete recovery of the animal can occur with treatment.

From a series of 78 dogs a formula has been developed which makes possible the accurate determination of the duration of tourniquet application necessary in the individual animal to produce irreversible shock. The calculation is made during each experiment and depends on the degree of blood pressure fall

plus the length of time the tonnuquets are applied. Thus the depth of shock can be controlled.

Plasma and solutions of gelatin and peetin have been used successfully as treatment for this type of shock.

Use of Concentrated and Normal Plasma in Shock

DR R. E. WILSON, DR S. O. LIVINGSON, MARTHA JANOTA, M. S., and DR HEINRICH NECHELES, Chicago. Shock was produced by graded bleeding in unanesthetized normal or dehydrated dogs. The severity of shock and the response to therapy were evaluated by the animal's general condition, circulating time, hematocrit, plasma volume, blood pressure, and arterial carbon dioxide content. Equal numbers of shocked animals in each group were infused either with normal (4-5 per cent) or with concentrated (15-20 per cent) canine plasma protein solutions. All animals received an equivalent amount of protein; the only difference between the two types of infusions being the total fluid volume.

Generally, following infusion, there was an improvement in blood pressure, circulating time, plasma volume and arterial carbon dioxide content. However, the response of the animals, both normal and dehydrated receiving normal infusions, was distinctly superior to that of those receiving the concentrated material, as shown by the more rapid and more pronounced clinical response. Furthermore, the blood pressure was better maintained subsequently when additional blood was withdrawn.

The arterial carbon dioxide gave the best index of the animal's condition after bleeding or infusion. Often although blood pressure, circulating time and plasma volume would return to normal levels, the carbon dioxide failed to rise above 10-25 per cent, and the animal would later die.

Despite an increase in plasma volume, the animals receiving concentrated solutions failed to survive as long as those receiving normal infusions. Apparently the gain in circulating intravascular fluid is at the expense of the extravascular and perhaps intracellular water with added damage to tissues already injured by oligemia and anoxia. In addition, rapidly infused concentrated solutions seemingly overburdened the heart for during and shortly after such infusions there often occurred a transient drop in the diastolic blood pressure and a bradycardia.

The state of hydration was important in determining the ability of an animal to withstand shock and respond to therapy. The dehydrated animals developed severe shock more rapidly than did the normal animals, and their response to therapy, particularly with concentrated solutions, was definitely inferior to that of the normal animals.

DISCUSSION

DR HEINRICH NECHELES, Chicago. When a dog or human being loses blood there is usually not hemoconcentration but hemodilution. The body tries to compensate for the loss of fluid and extracts available fluid wherever it can get it. Studies on dehydrated dogs subjected to hemorrhage have shown that available fluid decreases significantly. What happens when dehydrated dogs or human beings receive concentrated plasma or other concentrated colloidal solutions? They have to mobilize additional fluid in order to restore osmotic equilibrium of the blood. I believe, though we have no proof yet, that death may be due to dehydration of vital centers like the heart, kidney and centers of the brain. Another observation that we have made during these experiments is that with concentrated plasma, which contains large amounts of citrate, we may produce tetany. Concentrated plasma should not be used in cases that are dehydrated or in progressed shock. That brings up the advisability of using concentrated plasma in the armed forces. If we would have to transport double distilled water anyway, I wonder whether we should not use isotonic serum or plasma to begin with.

DR ELMER L. DEGOWIN, Iowa City. As some know, there is a controversy in this country among several groups of workers whether to use isotonic or concentrated plasma in the treatment of shock. The results of these experiments confirm observations made in England in the treatment of shock occurring in air raid casualties. I think there is no doubt from the evidence here presented and the work of others that isotonic solutions are better than are concentrated solutions. One word of explanation is required in view of the fact that soon there will be available to the armed forces a concentrated solution of

serum albumin for the treatment of shock. It has been realized that this is a compromise to conserve space, and directions on the packages of this product definitely emphasize the need for administering fluids either parenterally or by mouth to the patients who are under treatment.

DR R. E. WILSON, Chicago. It should be mentioned that at a recent meeting in New York Dr. C. P. Rhoads stated that the Committee on Blood Substitutes felt that hypertonic plasma solutions should be used with circumspection, particularly when dehydration is suspected. He contrasted the condition of the well hydrated patient in a hospital bed with that of the wounded soldier on the field of battle, not only is the latter often dehydrated before injury, but he loses additional fluid from his bleeding wounds and from vomiting. It is true that, in supplying blood substitutes for the armed forces, a compromise must be struck between the space allotted for storage of materials and the therapeutic efficiency of the materials used. But the ultimate consideration must be adequate and proper treatment for the wounded personnel. Consequently we should have more use of isotonic plasma protein solutions and less use of concentrated materials in the treatment of war casualties.

Experimental Studies on Burns

WILLIAM H. OLSON and DR HEINRICH NECHELES, Chicago. In previous work gastric motility was found greatly increased in most animals following body burns. Section of the vagus and splanchnic nerves did not affect this motility, but injection of atropine abolished it, suggesting at first that changes in the acetylcholine-esterase system might have occurred. Studies of the blood esterase of burned animals revealed no change.

An outstanding characteristic of burns is their immediate pressor effect on blood pressure in most experiments. A fall in blood pressure during the burn occurs rarely in a normal animal. This pressor effect appears to be due largely to vasoconstriction that causes a rise in blood pressure, although a severe loss in blood volume has occurred. These animals, although their blood pressure was relatively high, did not tolerate withdrawal of single or repeated small blood samples and often responded to this with a precipitous fall of blood pressure and even death. These animals with more or less normal or even high blood pressures were definitely in a state of shock, as shown by a high degree of concentration of the blood, low blood carbon dioxide (acidosis) and slow circulating time. One of the mechanisms responsible for this sustained blood pressure following burns may be the posterior pituitary gland, because we have been able to abolish the rise or maintenance of blood pressure following burns by hypophysectomy. Following this operation, blood pressure fell following burns, as is usually observed following traumatic shock.

The clinical application of these studies is that small doses of atropine should be given to all burned patients in order to avoid vomiting, ulceration of the stomach and so on. Secondly, blood pressure readings in burned patients may be misleading, and a normal or high reading may mask severe shock.

DISCUSSION

DR HEINRICH NECHELES, Chicago. We have done other experiments that Mr. Olson could not report. It is known from the fine experiments done at the Peking Union Medical College that there is a reflex afferent mechanism to the posterior pituitary gland. When this is interrupted, stimulation of sensory nerves will not be followed by an output of pressor substances and a rise in blood pressure. Therefore we have cut the pituitary stalk or the posterior lobe or performed total pituitectomy and have found that following this burns did not produce a rise in blood pressure. If we traumatize a limb we always see a drop in blood pressure. The pressor mechanism of burns seems to play quite a role in maintaining blood pressure until the animal dies, usually suddenly, at a level of blood pressure that may be called normal. At the same time other determinations indicated a serious physical condition of the animal, although the blood pressure was near normal. Pituitectomy may interfere with the capillary circulation, and consequent effects of burns may have nothing to do with the usual homeostatic mechanisms in shock. That remains to be shown. I believe we are dealing in part with a nervous and in part with a hormonal mechanism which both maintain or raise blood pressure in burns.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1922 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Waning of Tuberculin Allergy—The Pottengers encountered 41 children whose tuberculin reactions changed from positive to negative while they were under treatment for bronchial asthma, hay fever and chronic bronchitis. They all were positive to the first dose of purified protein derivative at the beginning of treatment and, while under treatment, failed to react to a subsequent similar dose and in some instances to the second dose of purified protein derivative. The positive reaction of 1 other patient became negative and again positive, this shows a decided lability in the reaction. A reaction was not considered positive unless there was erythema and the induration was at least 0.5 cm in diameter. In the children who failed to react on the repetition of the first dose of purified protein derivative it must be assumed that the effect must have been brought about by improving the patient's physiologic mechanism which was probably done by changing his chemical and physical tissue reactions. If a larger amount of tuberculin had been used a reaction might have been brought about. The instability of the tuberculin reaction (allergic) may be important in explaining the fact that a certain proportion of people who do not react to the first dose of purified protein derivative will react to the second dose. It is probable too that the time when the dose is given is important in the reaction. The adrenal cortex produces substances which have an antiallergic effect, and diet increases resistance. Resistance is physiologic, and immunity is an exaggeration of the normal physiologic mechanism. Both diet and the adrenal cortex were probably factors in the phenomena reported.

Tuberculosis in Nurses—An analysis of the sensitivity to tuberculin and the later history of 270 nurses who were affiliated with the Trudeau Sanatorium from 1936 to September 1941 is discussed by Schwartz. On arrival, all graduate nurses and 77 per cent of the students were positive to 10 mg or less of tuberculin. Of the nonreacting student nurses 25 per cent became positive by the end of their affiliation. Relapse has occurred in 1 of the 10 graduate and 3 of the 6 student nurses who had pulmonary tuberculosis on arrival at the sanatorium. Lack of a previous period of treatment seemed to be the chief

factor coincident with relapse among the students. In none of the graduate nurses but in 36 per cent of the tuberculin negative and 23 per cent of the tuberculin positive student nurses who had no demonstrable pulmonary disease on entrance did pulmonary tuberculosis develop later. The reactors in whom lesions developed were originally relatively insensitive to tuberculin.

Pleural Effusions in Pulmonary Tuberculosis—The pleural effusions investigated by Gordon and his co-workers in 80 selected cases (35 at necropsy) were studied with special reference to their pathogenesis and the mechanical factors favoring progression. From the pathologic changes, which in a measure explain the clinical manifestations, it is evident that the greatest number of cases of pleural effusion complicating pulmonary tuberculosis were directly associated with extension of subpleural tuberculous lesions and that the formation of the fluid was the precursor of serious complications, even though the amount of fluid was insignificant. The more acute the tuberculous process, the more frequently was effusion a complication. The more chronic and proliferative were the tuberculous lesions, the less often and the less serious was the effusion. There was no instance of pleural fluid in pneumonococcosis complicating tuberculosis, a possible explanation for this is the tendency of pulmonary fibrosis to hold the tuberculous process in abeyance. The age of the patient had no definite bearing. However, in young patients with chronic and fibrotic lesions fluid seldom developed, and when it did it was nonpurulent though tuberculous. Sulfadiazine has been of value in controlling superimposed pyogenic infection of the fluid. Quinine and urea hydrochloride used as a sclerosing agent aids in obliterating residual pleural spaces and pleurocutaneous sinuses.

Experimental Pulmonary Tuberculosis—Gunn and his collaborators studied observable differences between infection with virulent tubercle bacilli by the bronchial route into the pulmonary parenchyma in previously infected and in primarily infected dogs. Hypersensitivity to tuberculo-protein appeared in most of the dogs within a few weeks after intrabronchial or intratesticular injection of virulent tubercle bacilli. The maximal cutaneous allergy was usually reached within sixty days. When the first dose of human or bovine type bacilli was relatively small (1 mg or less) the primary lesion usually healed completely with cicatrization, but hypersensitivity persisted for a year or longer after healing was complete. Reinfection with an equal or larger dose of virulent bacilli, introduced intrabronchially three to twelve months after the first infection, resulted in a pulmonary lesion which did not differ significantly in size, composition or ultimate outcome from the primary lesion, that is, there was no morphologic evidence of a 'primary type' and 'reinfection type' of tuberculous lesion. Caseation, calcification, cavity formation and fibrosis did not differ appreciably in the pulmonary lesions of primary infection from those of reinfection, but there was a greater tendency for caseation to occur in the regional lymph nodes of the primary complex. Differences in natural (inherited) resistance to tuberculosis and differences in the size of the dose appeared to influence the results to an important degree but under the conditions of the experiments, the effects of acquired specific immunity and hypersensitivity were comparatively insignificant.

Application of Tourniquet to Extremity—Block's experiments to determine the systemic effects of the use of a tourniquet on an injured extremity reveal that its use should be avoided whenever possible but that if constriction is necessary the temperature of the distal ischemic and anemic part should if possible be lowered by artificial means.

Circulating Plasma Proteins in Dehydration and Malnutrition—Abbott and Mellors demonstrated that severe dehydration may exist even though vomiting has not occurred or has been minimal. They used unselected patients with carcinoma of the gastrointestinal tract or pyloric stenosis due to ulcer who had shown a moderate loss of weight and a diminished intake of food and fluid. Normal hematocrit values (erythrocyte counts and hemoglobin concentrations) and plasma protein concentrations may be obtained when dehydration is accompanied by malnutrition. In such conditions not only the plasma proteins but also the tissue proteins should be replenished. If adequate calories cannot be consumed orally intravenous or intrasternal alimentation should be resorted to. Adequate amounts of amino acids parenterally, will maintain a positive nitrogen balance when sufficient calories are given and thus an increase in the total circulating plasma proteins can be obtained.

Congenital Dislocation of Hip—Gill has encountered 204 female and 49 male patients with congenital dislocation of the hip, 69 had bilateral dislocations. The dislocations of 206 were reduced bloodlessly. There were 4 patients with bilateral dislocations in whom reduction was not attempted because of extreme malformation and other congenital deformities. After all patients with faulty or incomplete records are excluded there remain 126 whose hips were bloodlessly reduced. The percentage that remained reduced after one, two, three, four, five, six and seven, eight or nine years was respectively 17.5, 43.7, 35, 26.2, 22, 21.4 and 11.9. The successive percentages are progressively lower, for during the nine years 63 patients disappeared from the clinic or their result was undetermined. However, the result in these 63 cannot be considered a failure as in many the result was perfect, excellent, good or satisfactory when they were last seen. The percentages are therefore only relative. During the nine years 48 were operated on because of redislocation and 9 were not operated on. The hips of 12 were reduced by manipulation. In 2 the result in both hips (followed ten years) was perfect, in 3 (followed thirteen to twenty-seven years) one hip remained reduced and became perfect, while the other hip became redislocated and was operated on. Thus the result in seven of twenty-four hips was perfect. The author in the past has advocated an acetabuloplasty (shelf operation) as soon as a hip redislocated or when open operation was necessary. More recent observations have led him to delay such an operation, if possible, until the fifth year, in the meantime maintaining the limb in abduction in a plaster cast or brace to preserve the relation of the head of the femur to the socket. Failure of the operation at an early age may be due to the fact that the acetabular roof is largely cartilaginous, and the operative procedure damages its blood supply and prevents its conversion into bone. This resorption of the shelf, or buttress, has not been observed in patients more than 5 years of age. In forty-two extracapsular-buttress operations, observed for three to twenty years after operation, there were only four poor results. Periodic roentgen study alone can indicate the ultimate success or failure of the operation. Bloodless reduction has resulted in normal function for 16.7 per cent of the patients and for 30 per cent of those whose end result for eight and more years was known.

Sulfonamide Drugs in Hematogenous Osteomyelitis—Wilson and McKeever studied the influence of the sulfonamides on hematogenous acute osteomyelitis in 31 consecutive children entering the Los Angeles Children's Hospital from January 1939 to December 1941. The greatest effect of the sulfonamides

was on the infected blood stream, which was usually promptly sterilized. The incidence of death and of multiple involvement of the bone was reduced by routine sulfonamide therapy. An occasional patient with mild acute hematogenous osteomyelitis may recover with chemotherapy alone. Well timed surgical drainage of abscesses and pyogenic granulomas is not supplanted by chemotherapy in the treatment of acute osteomyelitis and it should never be assumed that recovery may or will result without drainage.

Flexion Treatment for Low Back Pain—A review of the literature suggested to Breck and Byson that flexion treatment of low backache due to a narrowed lumbar disk, regardless of whether the pain is due to a protruded disk or subluxation of the lumbo sacral or lumbar facets, is sound. Conservative flexion treatment utilizing new apparatus has been found efficient for home treatment. A new spine fusion procedure using a mortared inter-spinous bone block, has been successful in restoring the intervertebral inter-space to normal, in reducing accompanying subluxation and in giving internal fixation to routine spine fusion grafts.

Adrenal Extract in Fever Therapy—Edelmann and his co-workers tried to determine the underlying factors that caused adrenal extract to alleviate or reduce the severity of many of the ill effects (weakness, nausea, vomiting and herpes) of hyperpyrexia. The 12 subjects studied were suffering from syphilis of the central nervous system. They were treated once a week for ten weeks. Adrenal extract 6 cc was injected intramuscularly immediately after the first sample of blood was withdrawn and 4 cc after the patient was removed from the cabinet during control periods; placebos were injected. It appeared that adrenal extract prevented or reduced the fall in plasma sodium in some instance, had no effect on plasma potassium and may or may not have affected the plasma chloride. It appeared to have a decided effect in reducing fatigue and the rate of recovery after one or two treatments. If the results of five treatments with extract and the five without extract of each patient are averaged it is seen that the reaction is improved with extract. This was true whether the extract was used in consecutive or in alternate treatment. The first two fever treatments were tolerated better than subsequent treatments without extract. Although extract favorably affects fatigue and recovery the first time it is used, its effect is greater in subsequent treatments. The blood sugar fell in every instance in which it was determined when extract was not administered. When either extract or desoxycorticosterone was given the blood sugar rose somewhat. Extract caused a reduction in the concentration of sodium in the sweat. The total potassium excreted was reduced in some instances when extract was given. The results with total chloride were similar to those with total sodium. There were no significant variations in total protein, albumin, globulin and fibrinogen. The frequency and intensity of the other ill effects were also favorably affected. Desoxycorticosterone acetate had no beneficial effect. The retention of sodium when adrenal extract was given was insufficient to account for the amelioration of the unfavorable clinical reactions to fever therapy. It is suggested that extract may act on the central nervous system.

Studies on Measles—Stokes and his colleagues inoculated 250 supposedly susceptible and 5 presumably unsuitable children with measles virus grown on the chorioallantois of the developing chick embryo for three to six serial passages. The inoculation was by intranasal drip, inhalation, intradural

or subcutaneous injection. Typical reactions of extremely mild measles occurred in most of the inoculated children, that is, with Koplik spots, rash, fever, conjunctivitis and coryza but rarely with cough or malaise. Because of the nature of the reactions the measles virus as inoculated was considered to be modified and to produce an attenuated disease. The passage of the attenuated measles virus again through human beings from evidence obtained by a single human passage through several 'contact control' children, showed that it did not regain its virulence by such passage. There were no significant differences in the reactions to different routes of inoculation, to two different methods of preserving the virus material or to different dilutions of the inoculum.

Studies on Measles—According to Maus and her colleagues, 22 children who had been previously inoculated with egg passage measles virus were exposed by chance up to one year after their inoculation to children with active measles. Typical measles developed in 3 mild measles in 1, an extremely mild disease distinguishable with difficulty as measles in 3 and no disease in 15. Twenty-four similarly previously inoculated children were exposed by challenging injections of blood from patients with active measles. Typical measles developed in 3, mild measles in 2, an extremely mild disease distinguishable with difficulty as measles in 5, no disease in 13, and 1 child showed a slight nasopharyngitis without fever, rash or Koplik spots. The injection into suitable control children and monkeys of the challenge material caused measles, typical for the species, to develop. The measles virus used gave sufficiently encouraging results to warrant its further trial in larger groups of susceptible children under field conditions. Forty of the 46 children inoculated appeared to be completely or partially protected.

Sulfathiazole in Treatment of Dysentery—Rubens and his associates used sulfathiazole in the treatment of 17 children who entered the Cook County Children's Hospital because of frequent watery stools containing blood and mucus. There were 29 control children. Sulfathiazole was started from two to four days after the patient's hospitalization and continued until the stools were normal in number, color and consistency and until the cultures of three weekly consecutive stools were negative. The average daily dose of the drug was $1\frac{1}{2}$ grains (0.1 Gm.) per pound of body weight given in six equal doses at intervals of four hours. Nonspecific, supportive therapeutic measures, as indicated by the clinical condition, were employed. The 8 patients with clinical dysentery from whose stools positive cultures of *Bacterium dysenteriae* and *Salmonella* were obtained responded better to sulfathiazole than the 9 clinically identical patients whose stool cultures were negative. The ratio of the duration of disease after treatment was started is two and nine-tenths to four and seven-tenths days. The duration of diarrhea was shorter in the 8 patients after sulfathiazole was started than it was in the 13 similar patients treated identically but without sulfathiazole. The ratio of days of diarrhea after sulfathiazole was started was two and nine-tenths to eight and eight-tenths. Therefore sulfathiazole appeared to have definite value in the treatment of patients whose stool cultures were positive for dysentery or *Salmonella* organisms, but no statistically significant effect was demonstrable in those whose stools were negative for the organisms.

Tannic Acid Jelly and Silver Nitrate Dressing for Wounds—Walker suggests the use of tannic acid jelly and then a 10 per cent solution of silver nitrate as a rapid dressing to simulate the natural scab formed by coagulation and drying of blood and tissue fluid. The method fulfills satisfactorily the requirements of hemostasis, antiseptics, protection, splinting and appearance. The dressing is inexpensive, is easy to apply, may be reinforced by subsequent applications and is particularly useful in sites at which gauze is difficult to apply. Its use would

greatly decrease the need for gauze and adhesive tape. The laceration, abrasion, excoriation or other similar wound is cleansed, the skin is drawn together if necessary, tannic acid jelly is applied to the wound, the excess is removed after a few minutes and the 10 per cent solution of silver nitrate is applied. The film that results is an entirely satisfactory dressing.

Surgical Relief of Intractable Pain—Peyton states that for the relief of intractable pain at the University Hospitals 59 patients received seventy-eight subarachnoid injections of alcohol between January 1935 and January 1941, 9 had rhizotomies, 5 had tractotomies and 16 had chordotomies performed between July 1937 and January 1941. Unless the relief obtained, whether complete or partial, persisted until death or for at least two months in those surviving that long, the patient was classified as having no relief. Of the 59 patients having subarachnoid injections of alcohol 33 obtained complete relief, 15 partial relief and 11 no relief. Of the 9 in whom rhizotomy was done 7 were completely relieved and 2 had partial recurrence of pain several months after rhizotomy. The 5 patients on whom tractotomy was performed obtained complete relief. A postoperative ataxia of 1 patient disappeared in two weeks. Complete relief was obtained by 81 per cent of the patients having chordotomy for the relief of pain from incurable cancer.

Circulation Rate After Operation—Using the sodium cyanide method, Bellis and his associates determined the cubital to carotid and ankle to carotid circulation time in 191 cases about twenty hours preoperatively and postoperatively. Because the patient seems to respond better to a second stimulus of sodium cyanide than to a first, the response to injection was first determined from one of the cubital veins, and following an interval of five minutes an injection into one of the veins of the ankle was made. In no instance was the patient informed of the response expected. Occasionally the response was associated with symptoms suggestive of motor irritation which lasted less than a minute, in some slight temporary nausea was present.

but no alarming sequela ensued. None of the solution should be injected extravascularly, as local necrosis may follow such an accident. Usually the cubital vein to carotid and ankle vein to carotid time was shortened after major surgery. The average preoperative cubital vein to carotid and ankle vein to carotid body time of the 191 patients was seventeen and thirty-six seconds and the postoperative time was fourteen and thirty-two seconds, respectively. Circulation rates varied widely in patients with apparently normal circulatory systems. Acceleration of the blood flow postoperatively was probably related to the increased metabolic demands of the patient. Gravity retards the flow of blood from the upper and lower extremities, either when the position of the extremity is changed or when the longitudinal axis of the entire body is altered. Fowler's position delayed the return of blood from the lower extremities. The ankle vein to carotid circulation rate was shortened by active motion of the foot or toes and by elevating the extremity.

Therapy of Obstruction of Small Intestine—From June 1938 to April 1942, 130 patients with obstruction between the ligament of Treitz and the cecum were treated at the University of Minnesota Hospitals. The mortality in 110 was 15.5 per cent, the remainder were patients in whom obstruction of the small intestine was a minor incident in their death. At first it appears that less emphasis is being placed on conservative therapy at the clinic than was the case at the time of the last report in 1939. The reason for this, Dennis and Brown point out, is largely the success that has attended anastomosis in the presence of pronounced obstruction and intestinal gangrene, when performed by the closed technic. As the intestinal bacterial count can be reduced by the preoperative oral administration of succinylsulfathiazole in elective operations, the closed anastomosis with the local implantation of sulfathiazole finds its field of greatest usefulness in emergency obstruction cases. Only by the intelligent and combined use of the improved methods of intubation of the small intestine and of the newer surgical methods can further reductions in the 18 to 20 per cent mortality be accomplished. This is one fourth the mortality rate of two decades ago. Treatment consists in proper water and salt administration, decompression of the distended intestine by nasal tube or by catheter enterostomy if the tube is inadequate, parenteral administration of sugar, plasma and the like for a complete metabolic balance, resection of a gangrenous intestine and late operative restoration of intestinal continuity if the obstruction fails to relent spontaneously.

Conservatism in Surgical Management of Acute Regional Enteritis—Smithy believes that radical treatment is not indicated for patients in whom acute regional enteritis is initially encountered at a laparotomy for an acute abdominal condition. Only the phase of regional granulomatous inflammation of the intestine which is acute or subacute when first seen and which demands celiotomy at the time of hospitalization is considered. The 5 cases of acute regional enteritis reported by him were managed by simple exploration and appendectomy, and in none has the disease progressed. A strong tendency toward spontaneous healing is present in certain instances of acute regional enteritis. In 1 of the cases prompt healing followed primary closure of a perforated cecum in the presence of an acute process. Progress from an acute to a chronic condition under observation and thorough preoperative preparation by general supportive measures, transfusions and enteral chemotherapy is far more desirable than radical resection without preparation in an acute case. Appendectomy is incidental in the conservative form of surgical treatment, if the appendix is not removed it is eventually involved by acute granuloma, which may cause appendiceal obstruction from edema with consequent early rupture and peritonitis.

Thymus in Myasthenia Gravis—According to Sloan, the examination of 350 thymus glands, of which 150 were removed from patients dying suddenly, has confirmed the well known facts about the anatomy, histology and involution of the thymus. Fourteen of the 150 thymus glands contained lymphoid follicles with germinal centers in the medulla. The thymus glands of 10 patients with myasthenia gravis were no larger than many apparently normal glands. Examination of their thymus glands, none of which contained a tumor removed at operation revealed that there was some age involution, an increase in the number

of lymphocytes, in 7 an abnormal number of lymphoid follicles with germinal centers in the medulla, no epithelial hyperplasia and no constant change in the character and number of the Hassall corpuscles. At postmortem study there was no generalized lymphoid hyperplasia in the thymus glands from 6 patients with myasthenia gravis who had not been operated on. The thymus glands of 3 of 7 individuals with Addison's disease showed changes like those in myasthenia gravis. The glands of 5 acromegalic persons lacked involution, in addition 2 of the glands showed the changes found in myasthenia gravis. Of the 20 thymus glands examined from individuals with hyperthyroidism involution was lacking in 18 and in addition the changes in 5 were like those in myasthenia gravis.

The Gastric Mucosa as an Endocrine Gland—Abrahamson and Hinton have followed 21 men and 4 women with roentgenographically positive peptic ulceration who were taking orally combinations of $\frac{1}{2}$ to 1 grain (0.032 to 0.065 Gm.) of thyroid three times a day and $\frac{1}{60}$ grain (0.001 Gm.) of thyroxine intravenously once a week. To confirm specifically the action of these drugs on the gastrointestinal mucosa and to eliminate a rise in the basal metabolic rate some of the patients were placed on dimetrophenol. At the end of three months 6 patients were cured, 4 both symptomatically and roentgenographically and 5 were symptomatically improved but roentgenograms remained positive. During the following year 7 patients had a recurrence of acute symptoms and 1 a perforation. Several of these patients improved but later were unimproved and 2 came to operation. No difference was noticeable in those placed on thyroid and those placed on dimetrophenol. To ascertain the effect of estrogens on the activity of the gastric and the upper intestinal mucosa, 29 men with peptic ulceration of the duodenum were placed on various doses of theelin in oil. Thirteen to thirty-one intramuscular injections into the buttocks of 6000 to 50,000 international units were given daily. The men were followed up for one to five years. The only conclusion to be drawn from this therapy was that it caused a higher percentage of remissions in chronic duodenal ulcer (which lasted five to ten months) than is usual in controls. Of greater importance than the subsidence of symptoms in 82.1 per cent is the healing of the duodenal lesion in 42.8 per cent. This change occurred (as evidenced roentgenographically) in the presence of definitely increased free and total acidity. The conception that the gastric mucosa is a gland is presented and therefore that it is liable to influences similar to those which control the function of other endocrine glands. There are decided differences in blood hormone content between the sexes. These differences help to explain the sex discrepancy and age incidence in gastric carcinoma and benign gastroduodenal lesions. Further clinical and experimental work along these principles may throw further light on the problems of etiology, diagnosis and therapy of gastric carcinoma.

Tropical Eosinophilia—A new disease entity apparently peculiar to certain parts of India is described by Weingarten. The disease is characterized mainly by severe spasmodic bronchitis with paroxysms of coughing, leukocytosis, loss of appetite, loss of general strength and a decidedly high eosinophilia. At first (in 1934) an allergic state was thought the most likely explanation, but as more instances occurred the features of the disease argued against allergy. All but 3 patients seen during five years of consultant practice in Bombay lived near the sea. Not a single instance of the disease has been encountered by the author among the stationary inland population of India which has a dry climate with extremes in summer and winter. Though often the disease lasts for years, it is benign. There has been no opportunity to study a case at necropsy. Previously the diagnosis and treatment were either for pulmonary tuberculosis or chronic bronchial asthma. Only a leukocyte and a differential count can confirm or exclude the disease. In 1936 1 of the patients already under observation contracted syphilis and neoarsphenamine was given. His leukocyte count after four injections had fallen from 64,200 to 7,800 and the eosinophils had decreased from 71 per cent to 16 per cent. His subjective symptoms also vanished. But not until 1938 was it realized that this was no coincidence and since then patients have been systematically treated with neoarsphenamine, which proved to be a quickly acting specific. Injections were given every fourth day usually in a course of six, two each of 0.15, 0.3 and 0.45 Gm. The drug was dissolved in a 10 per cent solution of calcium gluconate to which 2 cc of a preparation of ascorbic acid was added. No untoward reactions were noticed. After the first two or three injections there is a tendency for

a further slight increase in the total leukocyte count as well as in the percentage of eosinophils, later they diminish abruptly, in some even before five or six injections have been given and in others only after the end of the course. Clinical symptoms usually completely disappear after the third injection. Patients treated in this way continue in good health.

Erythrocyte Suspension Transfusions—Transfusion of the erythrocyte suspensions prepared from the blood cells that remain after the plasma is removed is stated by Watson to be extremely useful in increasing the oxygen carrying capacity of the blood. Forty-six transfusions of the erythrocyte suspension have been given to 22 adults with anemia after hemorrhage, pernicious anemia, renal calculus, aplastic anemia, acute hemolytic anemia and chronic anemia. Patients usually reported that they felt better, had more energy and took a greater interest in their surroundings. The patients appeared to derive as much benefit (judged clinically) from an erythrocyte suspension transfusion as from a whole blood transfusion. No simple relationship held between the concentration of the erythrocyte suspension and the expected rise of hemoglobin in the recipient but when the aim of the transfusion was to increase the oxygen carrying power of the blood the benefit derived from a transfusion, in any instance, was directly related to the erythrocyte content of the fluid transfused. Group O blood should be used for making the suspensions, especially when such erythrocytes are available as a by-product of blood plasma separation. Suspensions should not be warmed before administration. A Riddell's pump should be utilized when concentrated suspensions are transfused. The maximum transfused to any outpatient should not exceed 1000 cc on any one occasion. When a large volume of group O erythrocyte suspension transfusions are administered to patients with other than group O blood, the risk of a reaction due to the transfusion of large quantities of isoagglutinin is reduced. The utilization of the suspensions for transfusion should reduce the calls made on blood donors.

Medical Journal of Australia, Sydney

1 1-22 (Jan 2) 1943

- Experiences of Salt Deficiency. J. M. Flattery. p. 5.
*Potato Diet in Peptic Ulcer. L. J. J. Nye. p. 7.

Experiences of Salt Deficiency—Flattery's studies of two years of an illness in navy men following exposure to a high atmospheric temperature, attributed to a salt deficiency through excessive and profuse sweating in a hot, humid, windless, enervating climate of the tropics, show that actually, even at rest (and apart from personnel working in the engine and boiler rooms), every person has periods of profuse and continuous sweating. The types of illness encountered were heat exhaustion, gastrointestinal illness and heat cramp. Sodium chloride to be of any use must be taken as an organized prophylactic measure and rigidly adhered to. The practice was instituted that every officer and man on the ship should take $\frac{1}{2}$ teaspoon of salt in water twice a day. On one ship the experiment of putting salt in the drinking water was bitterly resented. The educational method was much better. No ill effects of heat occurred when the routine was faithfully carried out. When salt was administered to affected patients, the response to treatment was almost immediate. The taking of $\frac{1}{2}$ teaspoon of salt in water twice a day should be instituted for all ships serving in the tropics, for ships during their passage through tropical areas (especially troopships) and also for all personnel living and stationed in tropical areas ashore.

Potato Diet in Peptic Ulcer—With the exception of the relatively few persons who are allergic to it, potato is an ideal food for patients with peptic ulcer. According to Nye, potatoes possess excellent food qualities, their caloric value is 25 calories per ounce (old, boiled potatoes), while that of milk is 19 calories per ounce. They are rich in minerals and in vitamins A, B₁ and C. The vitamin C content, which is greater than that of milk, makes potatoes especially valuable in the treatment of ulcers, since vitamin C exerts an important healing influence on wounds. Potatoes have an alkaline reaction and therefore assist in the neutralization of acid. When mashed with milk and butter potatoes form a bland, palatable food, which to most patients is a welcome addition to the usual list of monotonous milk foods. In the first stage the author advises two or more

potato feedings daily depending on the choice of the patient. For the patient's permanent diet potatoes should as much as possible be substituted for bread which has an acid ash (white bread contains 4 cc of tenth normal acid and wholemeal bread 17 cc per ounce). Many patients who were intolerant to milk have been successfully treated with a diet consisting mainly of potatoes. Potatoes are digestible. The popular fallacy that the skin of the potato contains most of the vitamins is erroneous. Recent investigation has shown that these increase in quantity toward the center of the potato. Of importance is the fact that much more food value is retained in the potato when it is baked in the skin.

Presse Medicale, Paris

50 217-240 (Feb 25-28) 1942

- *Sensations Provoked After Amputation and in Hemiplegia by Sympathetic Anesthesia and by Intra-Arterial Injection of Procaine Hydrochloride in Relation to Phantom Limb. R Leriche—p 217

- Traumatic Sciatica. Frequency. Treatment and Medical-Legal Consequences. S de Seze—p 219
- Small Epidemic of Bouillards Disease. C Blancardi and A Simonet—p 222

Sensations Provoked in Phantom Limb and in Hemiplegia.—Leriche reports 3 cases in which anesthesia of the sympathetic or intra-arterial injection of procaine hydrochloride provoked peculiar sensations. The first patient had undergone amputation of a hand in 1917. He experienced hallucinations of pain in 1937 after twenty years of normal life during which time he had never had perceptions of the absent hand and wrist. The stump was cold. The terminal cicatrix slightly below the middle third was soft and not indurated. There was no definite neuroma but palpation of the median and cubital nerve terminations was painful. Infiltration of the stellate ganglion with procaine hydrochloride was followed by a feeling of heat which descended down the arm, the forearm and into the hand. The patient was surprised to feel his hand hot and burning. The sensation subsided after a short while but on the following day and on the day after when infiltration was repeated the same sensations were experienced. The second patient had had his arm amputated in its superior third. He complained of excruciating pain on the inner aspect and the fingers of the absent hand. Intra-arterial injection of procaine hydrochloride produced a feeling of heat in the hand and the patient had the sensation as if movements of the fingers were interfered with by a swelling. The third patient a man with hemiplegia complained of a painful anesthesia and contracture. Following injection of procaine hydrochloride into the subclavian artery he experienced a sensation of heat in the arm, forearm and hand and two hours later was free from pain. Injection of procaine hydrochloride into the femoral artery was followed by a similar sensation of heat in the thigh, leg and foot along the exact course of the arteries. This is a curious phenomenon in a person with hemiplegia although otherwise the sensation would be normal. The author concludes that these cases suggest a new approach to the study of deep sensitiveness.

Nervous Accidents of Artificial Pneumothorax.—Vidal points out that statistics on nervous accidents complicating the induction of artificial pneumothorax are quite contradictory. They vary from 0 to 20 per thousand. Analysis by Vidal of fifteen statistical reports published between 1921 and 1937 and listing 153 accidents in a total of 419,029 pleural insufflations yielded the figure of 0.36 per thousand. Reports regarding their severity likewise vary some giving a mortality rate of 7.9 per cent and others of 16.6 per cent. The author reports 7 instances of nervous complications in a total of 8,000 insufflations. This is an incidence of 0.87 per thousand. One of the 7 resulted in a fatality giving a mortality rate for this group of 14.2 per cent. The first patient a girl aged 18 had had an effective pneumothorax on the left side which had been maintained for three years. Involvement of the other lung made advisable induction of pneumothorax on the opposite side. Two attempts at insufflation of the right side resulted in a generalized epileptic crisis. There were 2 other cases in which induction of pneumothorax brought on a generalized epileptic crisis. One patient developed localized epileptic and 3 hemiplegia. One of the latter patients died.

Sulfonamide Therapy in Gynecology.—Wenner reviews the results obtained with sulfonamide compounds in gynecologic hospitals of Switzerland. The effects in the treatment of uncomplicated gonorrhea were excellent. In the complicated cases the adnexal lesions were only slightly influenced although the gonococci disappeared as rapidly as in the simple cases. In nongonorrheal adnexal inflammations the therapeutic results were difficult to estimate; they did not seem to be considerable. The sulfonamides produced some favorable results in gynecologic operations. The prophylactic application in the operative field of infected or presumably infected patients has given good results. The effects of the sulfonamides have been favorable in the prevention of postoperative cystitis. The improvement obtained in febrile abortion was not striking. Sulfonamide therapy proved effective in counteracting the fever following radium insertion for carcinoma.

- *Should Soy Beans Be Cultivated in Switzerland? G Moser—p 979

Problem of Protein Supply During Wartime.—According to Jung the daily protein requirement is between 80 and 120 Gm and accounts for from 12 to 16 per cent of the calories. Persons who consume a relatively low number of calories usually take a higher percentage of protein because a person strives instinctively to take in not less than 80 Gm of protein. Most of the animal proteins not only are of relatively high value but also improve the taste and the satiating effect of food. The animal proteins should supply, if possible, 50 per cent of the human protein intake. Animals concentrate the vital amino acids from large quantities of feed; however the production of animal proteins involves great losses of food substances. Hogs return only from 25 to 30 per cent of the calories and chickens even less. Today many products which in normal times were waste must be utilized for human consumption. In this connection the author mentions the blood of slaughtered animals, skimmed milk and its products and grades of potatoes otherwise fed to animals. A dry preparation can be made from animal blood which is suitable for human consumption. Cheese from skimmed milk can now be processed in a more satisfactory manner. If Switzerland is to become entirely self-sustaining on its rather limited acreage proteins for human consumption must be obtained from products hitherto considered suitable only for the feeding of animals. In this connection the author calls attention to an early cut and rapidly dried clover. This clover has a high protein content. Experiments on rats proved that on a diet of bread and clover meal the animals thrived even better than on a diet of bread and skimmed milk. This indicates that it is not entirely a problem of protein but that vitamin A or E may account for the more favorable effect of the clover. Much would be gained if the clover meal could be utilized for human consumption because a hectare (2.47 acre) of land will yield 1,500 kg of protein if planted with this clover only 240 kg of protein if planted with cereal grains and even less if planted with potatoes. On the other hand intensive utilization of soil requires crop rotation and this will protect the population against a too one-sided diet.

Canned Fruits and Vegetables—There is no complete agreement so far on whether canned foods have the same value as fresh foods. The question of the vitamin content is of particular interest. This report presents an investigation of the problem. Cans are made of steel plate covered on both sides with a thin layer of tin. The opinion prevails that comparatively large quantities of tin are dissolved in the conserved food and exert a harmful effect on the human organism. The inside of the can often shows discolored streaks particularly in the case of vegetables with high protein content (peas and beans). The tin is attacked by amino acids and sulfur compounds which are split off from the vegetable proteins. In this process smallest traces of the metal are being dissolved in the vegetable fluid but they have no influence on the human organism. If the quantity of dissolved metal becomes larger it gives the product an unpleasant metallic taste, but even such food is not injurious to health, because tin is a nonpoisonous metal. Animal experiments with canned food containing large quantities of tin demonstrated the harmlessness. No cases of poisoning are known that could be traced to the tin content of cans. Studies on the vitamin A or carotene content revealed that these substances are only slightly impaired by canning and storage. Experiments on the vitamin B₁ content disclosed a minimal loss of 17 per cent in canning. The vitamin B content of vegetables is not at all impaired by the canning process. Vitamin C is water soluble and particularly in alkaline solution it is readily oxidized. Vitamin C is better preserved in those foods in which the juice has an acid than in those in which the juice has an alkaline reaction. Enzymes present in fresh vegetables have a destructive effect on vitamin C after harvesting. For this reason it is important that canning be done immediately after harvesting. In canned fruits vitamin C is preserved to a considerable extent but in vegetables the loss is higher. The vitamin D content of vegetables is slight and therefore can be disregarded in the consideration of the canning process. Vitamin E has a high resistance to oxygen and to heat and presumably is not lost during canning. Canned foods promote health and are capable of protecting the organism against avitaminoses. The protein fat and sugar contents of fruits and vegetables are influenced by canning in about the same manner as by ordinary cooking, that is, the loss in these substances is negligible.

Advisability of Planting Soy Beans—According to Moser, cultivation of soy beans gives promise of making Switzerland self sustaining during the war. Three years of observation have convinced him that if the right variety of soy bean is chosen and if it is properly treated, the cultivation will be successful, because soy beans will grow wherever grapes, maize and wheat will grow, up to an altitude of 700 meters. Climate is not the only decisive factor, the type of soil must also be considered. Acid and moist soils with a pH of less than 6 are not suitable. Agricultural experimental stations should investigate what varieties are most suitable for Switzerland. Bacteriologists should develop a nitrifying vaccine, like the German preparation "radizin," which stimulates the development of root nodules. The farmer should be given necessary information regarding soy bean cultivation, preparation of the soil, fertilization, inoculation of the seed, time, distance and depth of planting. In view of the shortage of agricultural labor, it should be emphasized that cultivation of soy beans can be done entirely with machines. The fact that soy beans require no nitrogen fertilization but, on the contrary, introduce nitrogen into the soil will be an added inducement. Potassium and phosphorus are the only fertilizers needed. The author concludes that introduction of the soy bean will cause as much change and improvement in human nutrition as did the introduction of potatoes two hundred years earlier.

- *Familial Placement of Minors A Bahia —p 137
 *Sulfanilamide in Therapy of Glomerulonephritis E Athayde —p 165
 Staphylococcal Empyema J Peroba —p 171

Familial Placement of Infants and Minors—Bahia reviews the history of familial placement of infants and minors and discusses indications and physical, moral and educational advantages of such a placement. The system does not always

represent an ideal solution of the problem of taking care of infants or minors as well as of mothers. The natural and most human solution of the problem will be the one which does not separate the mother from her child. The solution gives rise to several problems, which should in their turn be solved by the government or by the social service. Solution of the new problems is mainly concerned with giving parents medical care or means of earning money and work and moral aid to unwedded mothers.

Sulfanilamide in Glomerulonephritis of Children—Athayde reports encouraging results from the use of sulfanilamide in 20 cases of glomerulonephritis in children. The drug was administered in doses of 1 Gm daily. Fever and edema disappeared within three days, and the urine became normal. The drug was well tolerated.

 *Ascorbic Acid (Vitamin C) in Therapy of Pulmonary Tuberculosis I Roldán —p 261

Ascorbic Acid in Pulmonary Tuberculosis—Roldán advises the administration of ascorbic acid in pulmonary tuberculosis, especially in rapid loss of weight, frequent attacks of fever in the course of tuberculin and gold therapy, after operations and in pregnancy. The substance should be administered intravenously in daily doses of from 100 to 300 mg up to normalization of the ascorbic acid content of the blood. After the discontinuation of the ascorbic acid therapy the patient should receive liberal amounts of fruit juices, especially orange, lemon and tomato juices.

 Rheumatism and Its Relations to Microclimate of Dwellings B A Moreno —p 1244
 *Cod Liver Oils Possibility of Replacing Them By Argentine Products C A Grau —p 1248

Hormones in Treatment of Cardiac Neuroses—Diaz Mindurry investigated 8 cases of cardiac neurosis. Hormones given to these patients for endocrine disturbances exerted a favorable influence on their neurocardiac symptoms. The author directs attention to the importance of endocrine equilibrium. A woman aged 37, who had undergone a hysterectomy and bilateral oophorectomy, complained of repeated attacks of palpitation and feared serious heart disease, although cardiologic examination disclosed no anomaly. Treatment with estradiol counteracted the cardiac symptoms. Several other cases are reported in which the administration of gonadal or thyroid preparations improved existing cardiac symptoms.

Vitamin Content of Cod Liver Oil and Possible Substitutes—Grau determined the vitamin contents of cod liver oil preparations available in Argentina. He lists the vitamin A contents of thirty samples obtained on the market and shows that only nine of these had the 600 international units per gram which is the minimum requirement according to the pharmacopoeias of the United States and France. The author stresses that, because the war is curtailing the import of cod liver oil from the usual sources, efforts must be made to supply the needs of Argentina from fish oils available at home. He shows that it is possible to obtain liver oils with high vitamin A content from sea bass, sole, rays and sharks, to mention only fish livers sufficiently large to justify industrial utilization. It has been shown that oils obtained from the livers of these fish contain between 900 and 2,800 international units of vitamin A per gram. To make possible the effective utilization of the liver oils of the aforementioned fish, the fisheries of Argentina must be better organized and it must be made obligatory to sell the fish only after evisceration.

Services to the Orthopedically Handicapped A Report of a Study Made Under the Auspices of The Trustees of the Widener Memorial School for Crippled Children and the Board of Public Education School District of Philadelphia Louis P. Hoyer Director of Study and Charles K. Hav Assistant Director of Study Boards Price 30 cents Pp 115 with Illustrations Philadelphia 1942

This volume is a report of a study of services to the orthopedically handicapped made under the auspices of the Trustees of the Widener Memorial School for Crippled Children and the Board of Public Education School, District of Philadelphia. The work should be of major interest to persons engaged in vocational training or guidance and will be of minor interest to orthopedic physicians.

The authors discuss certain fundamental principles of vocational training and guidance for the orthopedically handicapped and set forth recommendations for improving programs for the physically handicapped. Although the subject matter may have general application, the authors devote most of their discussion to local problems of rehabilitation in and around Philadelphia. The reader is impressed that the authors are striving to effect improvements in the educational and vocational guidance system for the physically handicapped. These changes have a bearing on state and municipal legislation. The essentiality of having well qualified persons engaged in vocational guidance and rehabilitation and further the necessity of establishing well organized central administrative offices to carry out the operation of the programs is stressed.

In their approach to the problem of rehabilitation of the handicapped, the authors philosophy is sound. It places the emphasis on making the handicapped person self reliant cooperative and capable whenever possible of competing with other persons on an equal basis. Subjective considerations based on sympathy for the handicapped are not emphasized. Instead the emphasis is placed on the duty of society to offer facilities to the handicapped which will enable them to become socially and economically efficient members of a democratic society on their own merits. In other words the overall objective of the authors is to create a condition whereby adjustment is made in the case of the orthopedically handicapped to bring them whenever possible up to the standards of the normal group.

In the summary appearing at the end of the book, certain specific and important recommendations are listed which could well be adopted as criteria or norms for any broad program relating to the rehabilitation of the orthopedically handicapped. Of interest among these recommendations is the one dealing with provision for psychologic services to the handicapped—a type of service which has not always been given its proper important place in organized rehabilitation programs throughout the country.

Another important recommendation is that dealing with the type of instruction given under secondary education and adult education whereby the handicapped are provided instruction not only in the broad fields of education but also in specific skills that are required for jobs available to the orthopedically handicapped. The importance of this latter recommendation is apparent, since it is fundamental in at least affording an approach for the handicapped in achieving economic security or complete adjustment.

Familial Nonreaginic Food Allergy By Arthur F. Coca M.D. Medical Director Lederle Laboratories Pearl River New York. Fabrikoid Price \$3 Pp 160 with 13 illustrations Springfield Illinois and Baltimore Charles C. Thomas 1943

There is a large group of cases of food allergy in which the usual cutaneous tests do not aid in the diagnosis, many of the cases in fact present symptoms and syndromes which heretofore have not been recognized as allergic. These clinical conditions are herein grouped into a new category, which the author calls "familial nonreaginic food allergy, an unsatisfactory term offered only for the purpose of discussion and on the advice of a small group of allergists. Familial nonreaginic food allergy differs from the atopic category in that the hereditary influence is independent of the atopic inheritance the allergic antibodies are not demonstrable as they are in the atopic group (bronchial

asthma, hay fever and atopic dermatitis), many of the symptoms are not represented in the atopic group, and the allergic reaction practically always causes acceleration of the pulse rate. The importance of the new category is obvious in view of the author's estimate that at least 60 per cent of the population at times have clinical manifestations of food allergy. This book describes a new, accurate and comparatively simple diagnostic method by means of which one can determine which symptoms and syndromes are food allergic. The author places the patient on a sharply restricted trial diet for four days in order to establish the nonallergic range of the pulse rate. Other foods then are systematically added to the diet, one after another and their effect on increasing the pulse rate is carefully recorded. No food allergic range of the pulse of less than 22 beats per minute was observed in adults in cases under observation for at least five days. It was possible in most of the 51 cases studied to determine in the individual case all of the foods and other excitants of this category of allergic disease. Without exception in the first 44 cases in which the dietary treatment was completed, when the pulse rate reached the level in range recognized as normal for the individual the chief symptoms complained of completely disappeared and with them disappeared other symptoms which had not previously been considered allergic. When fully confirmed by other investigators, this diagnostic method and the dietary treatment of familial non-reaginic food allergy controlled by the pulse rate will broaden and perhaps tend to clarify the field of food allergy.

Le problème du cancer Par Charles Oberling Collection France Forever sous la direction du Professeur Henri Laugier Paper Pp 298 New York France Forever Montreal Les Editions de L'Arbre 1942

This is a well written account of the research into the fundamental nature and causes of cancer. It does not take up the control diagnosis or treatment of human cancer. The main part of the book is devoted to experimental cancer (one hundred and eighty-six pages). The other parts discuss the reasons for our interest in cancer, the evolution of the ideas about the nature of cancer, the theories of cancer and in conclusion, the question whether there are many cancers. The part on experimental cancer reviews the transplantation of cancer and the induction of cancer by various procedures and means. Unexpectedly, hardly anything is said about the cultivation of cancer cells outside the body or about the permanence of the change that takes place in a cell when it becomes cancerous and the transmissibility of that change to its descendants, generation on generation, apparently without the continued presence of the carcinogenic agent. The last section is a skilful comprehensive and withal reasonable augmentation in favor of the "virus theory of cancer" as opposed to the view that cancer is not an etiologic entity but an irreversible cellular reaction to various agents of diverse origin. The book is a striking example of literary skill and clarity in scientific writing and it will be read with profit by any one interested in fundamental cancer research. A good index would have increased its usefulness.

Mortalidad materna Estudio sobre 61 684 partos ocurridos en la Clínica "Eliseo Cantón" [años 1901 a 1940] Por el Dr. Charles Roust Tesista del doctorado en medicina Universidad Nacional de Buenos Aires Facultad de Ciencias Médicas Paper Pp 263 Buenos Aires 1942.

Today, when a cultural and sanitary unity of all countries of the American hemisphere is of fundamental interest, this monographic study is most timely, for in it the reader will find detailed statistics on maternal mortality in the largest Latin American metropolis during the last four decades and an accurate analysis of the reasons for its sharp decline—from 22.16 per thousand deliveries in 1901 to 3.37 per thousand in 1940. The greatest drop is due to the controlling of trauma and toxemia and to a lesser extent of hemorrhage and infection. For instance death as a result of obstetric trauma was reduced from 6.65 to 0.81 per thousand and that due to infection from 6.17 to 2.82 per thousand. All the other contributing factors such as nationality evolution of gestation pelvic deformities and length of labor are carefully analyzed. Tables and graphs add a great deal to the clarity of the thesis. This is a book that both the public health man and the obstetrician should read with considerable interest.

to know himself, his weaknesses and his nervous characteristics and to realize their effect on his ulcer. This understanding of his own reactions is most important, and the intelligent application of frequent feedings permitted thereby merely serves to counteract the effect of a wide variety of factors on his weak spot, his duodenum.

From the start the patient should realize that his ulcer is an individual problem and that he has to help in establishing the basis for the treatment. He should not feel that ulcer is a condition about which he has to feel fatalistic and hopeless. Once he is aware of his function as a detective in finding the various features of his personality, work or environment which are acting unfavorably on his ulcer he usually contributes many essential points of which he has been aware. Cure of the ulcer is dependent on the patient's protection of himself from himself in other words. Diet and antacids used in an intelligent fashion in order to prevent distress for one to two years can probably be considered to have rendered the ulcer quiescent. The evidence of the roentgenoscopic examination is of only moderate value in deciding about healing of the ulcer. If all the evidence after two years indicates satisfactory progress, however, the patient may consider himself in the third stage of treatment which involves prevention of further ulceration.

In the medical treatment of subacute duodenal ulcer it is necessary to insist on more intensive and more persistent care. The diet is liberalized more slowly, more rest is advised and in addition to the faithful use of feedings of milk between meals administration of antacids before and after meals is continued for many months and sedatives, as well as antispasmodics are prescribed for use during the first month or two of treatment after hospitalization.

Prevention of Recurrence—After the duodenal ulcer is considered healed, the patient must understand several aspects of the problem if he is to prevent future recurrences.

In the first place, his previous self analysis has shown him the ease with which his periods of sustained nervous tension, anger, worry, anxiety, excess responsibility or work may lead to acute flare-up of his ulcer. He may have learned the wisdom of avoiding such episodes. However, not every one is able to change one's life enough to avoid such strains all the time. If periods of strain cannot all be avoided, sufficient insight may be developed so that the patient can recognize the strains which are dangerous and prevent harm to himself by intelligent use of frequent feedings, antacids and sedatives during the period of strain.

In the second place, the patient must realize the danger of returning to any of his old habits which are likely to be irritating to his ulcer. He must stay away from alcoholic beverages, tobacco in all forms and the various spices, condiments and relishes which are so notoriously upsetting. Furthermore, he should make the taking of milk or milk and cream at 10 a. m., at 3-30 p. m. and at bedtime a habit which should last the rest of his life.

The fact that treatment has been successful enough so that the patient can liberalize his program and rely on his knowledge and judgment of his own ulcer to prevent further trouble serves to give him a sense of confidence and hope for the future.

SOME NUTRITIONAL PRINCIPLES OF MASS FEEDING

CAPTAIN GEORGE H. BERRYMAN
SANITARY CORPS, ARMY OF THE UNITED STATES

AND

COLONEL PAUL E. HOWE
SANITARY CORPS, ARMY OF THE UNITED STATES

Discussion in modern dietetics and nutrition occasionally leaves the impression that proper feeding and the attainment of adequate nutrition are dependent on following a set and rigid food pattern. Thus we meet with rather wide acceptance of the idea that almost every day every one should pattern his food intake somewhat along the following lines: one serving of meat, one egg, a pint of milk, a certain quantity of grain products, two vegetables, one of which is a leafy green or yellow and two fruits, one of which is citrus. We see large displays exhorting one in no uncertain terms to "eat these EVERY day," followed by a list of well selected foods known to be rich in nutritive value.

Such a plan for the general public is well conceived, for the nutritional significance of foods or food groups is not common knowledge. By following such a plan the lay person has a fair chance of attaining his daily nutritive requirements. However, for those who are more intimately concerned with nutrition it is basic to recall that nutritional adequacy is attainable by a wide variety of means and that it is not restricted to one or a few food patterns. In times and situations such as the present, when the normal wide variety of foods is decreased because of the ramifications of waging war, it becomes most important to appreciate the nutritional significance of foods and food groups, so that restriction in kinds or quantities of certain types of food may be offset by the use of other foods of similar types.

In the substitution of one type of food for another however, it is important to maintain, as far as is practicable, the nutritional value of the diet as a whole. In other words, such substitution should be made on the basis of nutritional equivalence. The principle of equivalent substitution is most easily followed if foods are grouped together on certain bases which have proved valuable in the application of nutritional principles to mass feeding, namely similar nutritive content, unique contribution to the diet or special function in the diet. In this way all foods fall into seventeen food classes, which will be discussed further in some detail.

It is becoming increasingly important for those concerned with the nutrition of the armed forces and of the civil population to think along basic nutritional lines. As a matter of fact, this is being forced on us by the sequence of events. As far as the soldier in campaign is concerned, it is apparent that, as the problems of transporting food in increasingly large quantities over long distances become more and more acute, many familiar foods will of necessity be dropped from his daily fare. Already the logistic advantages of the dehydrated, desiccated, compressed and concentrated types of food have resulted in their increased use by the soldier. With regard to civilians, as the problems of reaping crops, transportation, supplying the soldier

Captain Berryman is the executive officer of the Food and Nutrition Division, Army Medical School, Washington, D. C., and Colonel Howe is chief of the Nutrition Branch, Medical Practice Division, Office of the Surgeon General, Washington, D. C.

and supplying other countries grow in importance so will the availability of many common foods be decreased. In turn there will be a departure from what one might, for convenience term the "luxurious" choice of foods. With this change there should come a better realization of the ways in which adjustments and changes may be made in the ordinary diet without harmful effect. It should be recognized that certainly no one food item, and frequently no one food class can be called "indispensable."

The attainment of adequate nutrition depends on the provision, consumption, physiologic absorption and utilization of certain indispensable nutritional components. Foods and food classes are of importance primarily from the standpoint that they provide these components. Foods should be secondarily important because of their palatability and attractiveness which encourage their consumption in quantity and the consumption of other foods. It is true that on occasion the secondary consideration may assume equal importance with the primary. Fundamentally, however, it is the provision of a certain quantity of energy, protein, minerals and vitamins that is the important problem. It is comparatively unimportant how these nutritive components are provided, whether for example vitamin C is provided exclusively by a daily citrus fruit, by a daily leafy green vegetable or by a combination of the two. Whether one obtains one's calcium from fresh milk, evaporated milk or dried milk is not basically important, except that the general acceptability of the food product affects the amount eaten and therefore the amount of calcium obtained. It is pertinent to point out, although in a light vein, that if the wall plaster could be made palatable and esthetically desirable it might be used for the purpose of furnishing part or all of our needs for calcium. With similar reservations a rusty nail might serve as a source of iron, as might likewise drinking water which had been stored in an iron cistern. In the attainment of adequate nutrition, therefore, it is necessary to appreciate fully why, nutritionally speaking, a food is used.

It is not practical to attempt to remember the nutritional value of each food used daily by the average person. Moreover, individual nutritive values—the concentrations—are of limited importance from the aspect of practical mass nutrition. For example, strawberries are an excellent source of vitamin C in themselves, but when it is considered that the average daily consumption of strawberries over an appreciable length of time is usually very small it becomes apparent why they are in themselves rather unimportant as a significant constant source of this vitamin. In effect, this is to say that there are two equally important aspects to the attainment of nutritional adequacy—the quantitative and the qualitative. It is desirable to remember in this regard that consumption in large quantity of a food (or food class) may frequently impart nutritional importance to the food or food group concerned, even though its concentrations of nutrients may be rather low. For example, potatoes are a rather dilute food, from the standpoint of vitamins—the concentrations of vitamin C and the B vitamins are not strikingly high. Yet when considered in terms of the quantity consumed by the soldier, the potato makes a rather significant contribution to the soldier's daily intake of these vitamins.

The entire problem of interpreting dietaries is simplified by considering not individual foods but instead

food classes. On the basis of similar nutritive value, unique contribution to the diet or special use in the diet, all foods can be classified into seventeen food groups as previously mentioned. These are (1) meats, fish and poultry, (2) eggs, (3) milk and milk products, (4) fats with a relatively high vitamin A content (butter and fortified margarine), (5) other fats containing little vitamin A (cooking oils and the like), (6) cereals and grain products, (7) beans and other legumes, dry, (8) sugars and syrups, (9) vegetables, leafy green or yellow, (10) tomatoes, (11) citrus fruits, (12) potatoes (Irish), (13) vegetables other than leafy green or yellow, (14) fruits other than citrus, (15) dried fruits, (16) beverages (coffee, tea, cocoa) and (17) miscellaneous. This classification has been discussed in detail elsewhere. Fifteen of these groups are nutritionally significant, although the last two namely beverages and miscellaneous, are dietetically important in that they may on occasion exert an indirect influence on nutritional considerations. After conversion to unit intake per man or per hundred men it is possible to appraise the diet nutritionally. By the use of such a plan one recognizes that what may appear to be a somewhat low intake of one class of foods may be offset by an increased intake of another class. For example, a low intake of tomato products may be offset with regard to vitamin C by an increased intake in the leafy green or yellow vegetable class or by sufficient citrus fruit or vice versa. In similar manner a decrease in the intake of leafy green or yellow vegetables may be offset with regard to vitamin A by an increased intake of liver in the meats class or by cumulative slight increases in other classes such as eggs, butter and tomatoes. In effect, then, nutritional adequacy is attainable by a wide variety of means and is not limited to any one set food pattern. For families this principle is conveniently applied on a weekly basis. The total amounts of food groups used by a family may be varied interchangeably, depending on the relative availability of foods, provided, however—and this is most important—that nutritional adequacy is maintained or not decreased appreciably. The proper technic is to determine the number of pounds (or fractions thereof) per person of each food group which has proved acceptable to the family on the basis of its food habits, level of activity, income level, environment and other factors. Once this composite picture is established variations can be introduced without adversely affecting the nutritive level of the diet, if substitution is made on the basis of nutritional equivalence. Indeed, certain types of substitution, if judiciously chosen, have the effect of actually improving both the acceptability and the nutritive value of the diet. The principle involved is illustrated in table 1 which has been prepared for use in military circles. The principles are widely applicable however.

It is obvious that the key to proper substitution is a thorough knowledge of the nutritional significance of food groups. For the Army this significance is apparent from table 2. It is unlikely that there would be any major shift in importance in terms of civilian diets since field ration A corresponds roughly to a liberal civilian diet. In table 2 is indicated the approximate contribution of food classes in terms of percentage of the daily nutrients as planned from May 1941 to April 1942 U. S. Field Ration A. The figures in parentheses illustrate the shift in importance when probable conservative deductions for preparation procedures are

applied to the levels of some of the labile vitamins, namely thiamine (in meats and potatoes) and ascorbic acid (in vegetables undergoing cooking and other preparation procedures). (Similarly deductions should be applied to other vitamins, however our present information on cooking losses is not quite as extensive for the other vitamins as it is for the two mentioned.) It is noteworthy that foods consumed in the raw state or those undergoing only slight preparation and cooking, will contribute a higher percentage of the daily intake of nutrients as actually consumed and that this increase in importance varies directly with the extent of nutrient destruction caused by preparation procedures.

Some broad conclusions are apparent from this table. These conclusions are surprisingly different from some which are commonly accepted. For instance, 1 Eggs, while contributing certain amounts of many nutritive components are actually for the soldier a good source of riboflavin only. (It must be remembered in this regard however that they are quite important in cooking and baking and therefore they obviously have a masked importance in influencing the quantitative consumption of some of the other foods.) 2 Milk products (including evaporated milk and cheese) are of importance for their contribution of protein and riboflavin in addition to their commonly accepted importance with regard to calcium and phosphorus. 3 Grain products are of importance for a number of nutritive essentials, including not only calories and the B vitamins but also protein and certain minerals. 4 Legumes, although frequently spoken of in relation to their being a good source of protein are in addition a fair source of iron. 5 Syrups and sugars contribute chiefly calories (although they may have additional importance from the standpoint of "pleasure" and in influencing favorably the acceptance of other food groups). 6 The leafy green or yellow vegetables are of importance not only for their vitamin A potency but also for vitamin C. 7 Tomatoes frequently considered to be a major source of vitamin C, may not really be so at all, they are, however, a good means of providing this vitamin because of their general popularity and the quantities in which they will ordinarily be consumed. 8 Attention should be drawn to the potato. It may be important not only for vitamin C but also for certain of the B vitamins as well as for certain minerals. In the quantities consumed by the soldier, it is a most important food in the diet. In fact, in terms of returns per acre as well as an all-round nutritional contribution, it is one of the most valuable vegetables in common use. 9 Fruits other than citrus, while sometimes of significance individually, as a group contribute mainly to the pleasure of the diet.

In passing, it might be pointed out that the chart indicates that for the soldier meats contribute significantly to nine out of twelve important nutritive components, milk products to five, grain products to eight and potatoes to two. At first glance this appears to give emphasis to the old idea that if we get sufficient meat, potatoes, bread and milk all is well nutritionally. It is at this point, however, that we must turn our attention to the problems of palatability and acceptability. It should be obvious that the day after day acceptability of a diet consisting of only these four types of food would be quite limited. The legumes, the fruits, the eggs, miscellaneous items and the other

TABLE 1—Food Substitution Chart*

Certain factors must be kept in mind in substituting one food for another in a planned menu: (a) that it is acceptable in relation to the other foods and, if possible, acceptable to the majority of the command and (b) that it is nutritionally equivalent or, if not, that proper adjustments are made.

Certain foods satisfy the first requirement but not the second. In such cases it is necessary to make adjustments in the quantities or kinds of other foods that possess nutritive values displaced by the food substituted. For example, rice substituted for potatoes reduces the intake of vitamin C and certain of the B vitamins both of which tend to be low in most diets. It is desirable therefore to be sure that other foods carrying these nutrients are not low in the menu. It may be necessary to increase the amounts of foods.

A Group 12 Potatoes

Potatoes Irish

Baked, boiled (with or without skins), French fried, fried, hashed brown, Lyonnaise, mashed, O'Brien, parsleyed, roast brown, salad, scalloped.

(Potatoes sweet)

Baked, boiled, candied, scalloped.

B Group 7 Legumes (Beans and Peas) Dried

Beans, large

Baked, boiled, soup

Beans, kidney

Baked, boiled, salad, soup

Beans, kidney

Chili con carne

Beans, lima

Baked, boiled, creamed, soup, with bacon or ham

Peas, black eye

Baked, boiled

C Group 6 Grain Products

Hominy, white

Baked, boiled

Hominy, blue

Boiled

Macaroni

Baked, boiled, salad, scalloped with cheese or tomatoes

Noodles

Baked, boiled, salad, with cheese or meat

Rice

Baked, boiled, curried, pudding, Spanish, etc.

Spaghetti

Baked, boiled, Italian, with cheese or tomatoes, etc.

D Group 9 Leafy Green or Yellow Vegetables

Asparagus

Baked, buttered, creamed, salad, soup

Beans, string

Boiled, buttered, salad, Spanish

Beet greens

Boiled, buttered

Broccoli

Boiled, buttered, creamed

Brussels sprouts

Boiled, buttered, creamed

Cabbage, green

Boiled, buttered, creamed, fried, salads

Carrots

Baked, boiled, buttered, candied, creamed, fried, salads, etc.

Chard

Boiled, buttered, creamed

Collards

Boiled, buttered, creamed

Kale

Boiled, buttered, creamed

Lettuce

Salads

Okra

Baked, boiled, etc.

Parsley

Garnish, etc.

Peas, green

Boiled, buttered, creamed, salad, soups, etc.

Peppers, green

Baked, salads, sauces, stuffed, etc.

Pumpkin

Baked, custard, mashed, pie, etc.

Spinach

Boiled, buttered, creamed, salad, soups

Squash

Boiled, mashed, pie, etc.

Tomatoes, canned, fresh

Baked, grilled, salads, scalloped, sliced, stewed, stuffed, etc.

Turnip greens

Boiled, buttered, creamed

E Group 13 Other Vegetables

Beets

Boiled, havyard salad

Cauliflower

Boiled, buttered, creamed, fried, salads

Celery

Braised, creamed, salads, soups

Corn

Buttered, cob, creamed, fritters, pudding, scalloped soups

Cucumbers

Garnish, salads, etc.

Eggplant

Baked, fried, scalloped, etc.

Lima beans

Baked, buttered, creamed, soups, succotash

Onions

Baked, creamed, fried, salads, sheed soup, stewed

Parsnips

Baked, buttered, fried, etc.

Radishes

Garnish, salads, etc.

Sauerkraut

Baked, boiled, fried, etc.

Turnips, roots

Baked, boiled, creamed, sliced, fried, mashed, etc.

- 1 Foods within each group may be roughly substituted for one another without seriously affecting the nutritional value of the menu. However, a notable exception is the substitution of Irish potatoes for sweet potatoes. In this case sweet potatoes do contain an appreciable amount of carotene (the precursor of vitamin A), whereas Irish potatoes are lacking in this substance.
- 2 From a nutritional (particularly vitamin) standpoint, foods from groups 12 and 7 (A and B) may be profitably substituted for group 6 foods (C), but not vice versa, and group 9 foods (D) may be substituted for group 13 foods (E) but not vice versa.
- 3 If it is necessary to substitute a food of less nutritional value for another food (as beets for spinach) then another substitution (as carrots for onions) should be effected as soon as possible to offset the former. In this way there will be the least impairment of nutritional adequacy.
- 4 When substituting the food groups as under paragraph 2 it is not important to readjust the substitutions as under paragraph 3 and a more variety is desired, as the substitutions will provide additional nutrients.

* Material developed in connection with course in Food and Nutrition, Army Medical School.

classes which do not appear to be important in terms of major contribution do, nevertheless, make a minor contribution and may actually, by their effect on palatability and acceptability be the controlling factors in the complete consumption of the diet and therefore assume great indirect importance in the attainment of nutritional adequacy. We usually recognize this by stating that the well rounded diet is the one which is most likely to provide optimal nutrition.

With this background, and using the concept of varying and nonrigid quantities of food groups we may review some of the commonly accepted ideas about the nutritional importance of certain foods. As far as evaluation of the soldier's diet is concerned let us theoretically decrease or entirely remove certain of the food classes from the daily fare in order to become more familiar with the net nutritional effect and thence,

to the supply of provitamin A and ascorbic acid, and possibly of iron where the dark green leafy vegetables are concerned. It is interesting to note that at least for the soldier the planned level of vitamin A would still be much higher (owing to small quantities of liver) than that recommended by the National Research Council, and that vitamin C would also remain at acceptable levels, even after deduction for conservative probable losses in cooking. However, the decrease could well be offset, at least with regard to provitamin A, by an increased intake of such food groups as tomatoes and dried fruits. Liver is extremely high in vitamin A, another possibility would lie in increasing its intake. As far as vitamin C is concerned, tomatoes (either canned or fresh) would be valuable as replacement, and potatoes or vegetables other than the leafy green or yellow type could be used for additional quantities of

TABLE 2—Nutritional Contribution (Per Cent) of Various Classes of Foods Based on Food Prescribed for U S Army (May 1941–April 1942 Field Ration A)

Food Group	Calories	Protein	Fat	Carbohydrate	Calcium	Phosphorus	Iron	Vitamin A	Thiamine	Riboflavin	Nicotinic Acid	Ascorbic Acid

* Contributed almost entirely by liver † International units

Note: A daily contribution by a food of 10 per cent of the total intake of a nutrient is arbitrarily used as evidence of a major contribution to the dietary.

by deduction, with the purpose that certain foods serve in the diet as well as with the possibilities of replacing them by suitable substitution.

1 "Eat one egg almost every day." Let us remove the eggs entirely. The effect is to lower somewhat the intake of many of the nutritive components, since the egg contains small amounts of most of them. However, from the quantitative standpoint the most serious effect on the day's planned intake of nutrients for the soldier is to lower the riboflavin by about a third of a milligram. Obviously it is possible to supply the riboflavin thus removed by an increased intake of another class of food. One means of doing this would be by the addition to the diet of small extra quantities of liver, which is extremely rich in riboflavin. Other cuts of meat, usually not in great demand, are also quite rich in this vitamin. Whole grain products would be valuable, and should riboflavin be added to enriched flour this would provide another means at our disposal. Milk products, when available, would likewise fill the breach.

2 "Eat two vegetables every day, one of which is leafy green or yellow." Remove all leafy green or yellow vegetables. If it were feasible to delete from the diet this important class of foods entirely, the most serious direct nutritional effect would be with regard

to the supply of provitamin A and ascorbic acid, and possibly of iron where the dark green leafy vegetables are concerned. It is interesting to note that at least for the soldier the planned level of vitamin A would still be much higher (owing to small quantities of liver) than that recommended by the National Research Council, and that vitamin C would also remain at acceptable levels, even after deduction for conservative probable losses in cooking. However, the decrease could well be offset, at least with regard to provitamin A, by an increased intake of such food groups as tomatoes and dried fruits. Liver is extremely high in vitamin A, another possibility would lie in increasing its intake. As far as vitamin C is concerned, tomatoes (either canned or fresh) would be valuable as replacement, and potatoes or vegetables other than the leafy green or yellow type could be used for additional quantities of

this vitamin. An increase of citrus fruit would of course, be the easiest solution.

3 "Eat two fruits daily, one of which is citrus." Let us consider the possibility of an entire lack of citrus fruits. The chief loss would concern vitamin C. Ways of offsetting this are apparent from the discussion in the preceding paragraph. Furthermore, the possibility of sprouting legumes and grains as an accessory source of this vitamin should not be overlooked.

4 "Eat a certain quantity of cereals and grain products every day." Table 1 indicates that grain products are next in importance to meats for the soldier as far as supplying essential nutrients is concerned. A decrease by two thirds of the planned intake however would have its most striking effect on the caloric and thiamine levels. As far as the former is concerned it is obviously possible to supply them otherwise in the guise of fats or of sugars or syrups and the like. The thiamine which would be removed could well be furnished by a somewhat increased intake of meats or by the cumulative effect of increasing the amount of legumes, eggs and certain vegetables. It is unlikely, however that grain products will undergo a drastic decrease in the diet. It is more probable that their consumption will be increased as other foods become less obtainable.

5 "Eat one serving of meat (or fish) every day" Reduce the intake of meat. In view of the present rationing of meat it is appropriate to consider the effect of lowering the consumption of meat. Let us consider a lowering of meat intake from approximately 0.85 pound per man daily to less than one half that level—let us say to 0.4 pound, a decrease which is in the realm of theoretical possibility, although it would admittedly be at variance with the food habits and desires of the soldier. The outstanding effects would be to decrease the caloric intake by about 500, protein by about 30 Gm, phosphorus by 300 mg, iron by 4 mg, thiamine and riboflavin by 0.4 mg each and nicotinic acid by about 10 mg. As far as the calories are concerned, there are many important sources, chief among which may be named the fats, the sugars and syrups and grain products. The decrease of 30 Gm of protein would leave a level of 100 Gm, which is above the recommended daily allowance of the National Research Council. However this loss could be offset by an increase of eggs and milk within the animal sources, and grain products and legumes in the nonanimal class. It is worthy of note that such increases would at the same time provide certain of the B vitamins. Whole grain products or enriched flour products would however be the most logical means of increasing the latter. Potatoes are also a good source of some of the B vitamins particularly when consumed in quantity. It is a definite possibility, therefore, that the most practical way of offsetting a decrease in available meat products will be found to be by increasing the consumption of grains and potatoes.

These few examples have been concerned with common beliefs arising from a policy of limitation to a single or only a few food patterns. Not all of the possibilities have been discussed. For example little has been said about the tenet "one pint of milk per day for every person" (although this is less easily changed than some of the other beliefs, since milk and milk products are most important for calcium and riboflavin). Without arbitrarily attempting to single out any one type of food the possibility of attaining nutritional adequacy by the use of a number of food patterns has been demonstrated. On the other hand, it is recognized that in practice certain complicating factors may arise. Not the least important among these are the difficulty of changing established food habits, the matter of cost and the current availability of foods. These problems cannot be passed over lightly. However the basic concept of providing proper nutrition without being bound to use certain foods every day still stands.

It is appropriate to mention briefly at this point the civilian habit of depending on vitamin pills and concentrates as an open sesame to proper nutrition. The following order is in effect for the military, and it appears to be equally applicable elsewhere.

"Vitamins are essential to the health, welfare and fighting efficiency of every soldier, but it is more desirable to obtain them in their natural form from foods consumed rather than through the use of synthetic products in tablet form. There is no evidence that vitamins in excess of daily requirements are useful. In the event vitamins are required in tablet or capsule form to supplement the ration, they will be furnished in accordance with the following instructions:

"No requisition for vitamin concentrates to supplement the ration should be submitted until a medical

officer or nutritionist has analyzed the diet provided from the menu in use. The conclusions of such a review should be based on the nutritional value of the foods actually available and not merely on the absence of fresh foods. In the event it is determined that available foods are being properly prepared, served and consumed, and still a requirement for vitamins to supplement the ration exists, a requisition should be forwarded with a statement that the diet is inadequate and suitable foods cannot be obtained in quantities sufficient to meet vitamin requirements. Specific evidence of inadequacy should be cited. The requisition will state that the surgeon has approved the quantity required as appropriate for the strength and period involved."

It is true, on the other hand, that there may be certain occasions when vitamin supplementation to civilian diets may be indicated. It is not intended to frown on the use of accessory vitamins under all circumstances. However their use should be predicated on the basis of a probable or possible deficiency in the diet as determined by a rough evaluation of the customary food habits involved. Routine use of such products is rarely necessary (except in disease or pregnancy and lactation), nor is it economical. This is particularly true when it is remembered that an excess of vitamins is discarded by the body and therefore is of no aid whatever to the individual.

SUMMARY

In recapitulation, it is possible to obtain a nutritionally complete diet in a number of ways. A knowledge of food classes and their approximate nutritional significance is a distinct aid in this regard and forms the basis for equivalent substitution of foods. While a single food pattern may be the practical solution in the attainment of adequate nutrition for the individual lay man, yet it is quite unnecessary to gage the adequacy of a diet in regimented terms. Nutritional adequacy is attainable by a variety of means and it is not necessarily restricted to one set food pattern. The intelligent use of foods presupposes a thorough knowledge of what, nutritionally speaking, the food group may be expected to contribute in normal times, as well as its potentialities when logistics or restriction of supply of certain types of food interfere with "the pattern." Our nutritive requirements are for nutrients, not for certain foods as such.

Food Likes and Dislikes—Dressing up may overcome psychic aversion to a given food, but it will never disguise the effect if the patient belongs to that group of individuals who are sensitive or allergic to certain foods. One friend of mine was surprised to note when he ordered Scotch woodcock that it was not a bird. Another individual wanted to try frogs' legs and actually ordered them until some one suggested that frogs ate living things, even cockroaches, and so frogs' legs as a delicacy were debarred from her menu. Many persons discontinue eating a certain food because that particular food was the one they happened to be eating when an acute attack of indigestion occurred. The indigestion may actually have been biliary colic, with the food in question in no way responsible. Time and again one food after another may be cut out, reducing the diet to almost nothing because the ingestion of each food in turn was followed by pain. If the truth be told, the taking of only water will occasionally induce pain if a penetrating ulcer or a stone in the cystic duct is present.—Rehfu Martin E. *Indigestion Its Diagnosis and Management*, Philadelphia, W. B. Saunders Company, 1943.

A SOLVENT VAPOR, CARBON
DISULFIDEABSORPTION, ELIMINATION, METABOLISM
AND MODE OF ACTION

BOSTON

Before the toxic symptoms elicited by a solvent vapor can be diagnosed and treated intelligently it is helpful to know certain physiologic reactions of the compound. They are (1) the rate and extent of absorption into the individual's body, (2) the rate of excretion, (3) the rate and the amount of the compound metabolized by the body, (4) the site of action of the vapor and (5) in what manner the toxic action is elicited. In this paper we have attempted to give a partial answer to these questions as they apply to carbon disulfide (CS_2).

The absorption of any solvent vapor into the blood stream takes place primarily by way of the alveoli. The amount of vapor absorbed is regulated mainly by the vapor concentration breathed, the length of exposure and the coefficient of distribution¹ of the solvent between air and blood and between blood and tissues. This last point should be particularly stressed because further absorption of a volatile solvent does not take place after blood and tissue saturation at a particular vapor concentration has been reached except as the compound is metabolized and excreted by channels other than the lungs. Furthermore as Henderson and Haggard² have pointed out the greater the solubility of a solvent vapor in blood and tissues the more rapid is the absorption but the less rapidly is the saturation point reached. Conversely, the lower the solubility of a vapor in blood and tissues the more rapidly is the saturation point reached. In the case of a solvent vapor like ethyl alcohol which has the high coefficient of distribution between air and blood of about 1150,³ it is not possible for the body of a person to become saturated during a working day or even by continuous exposure for several days. This would be true even if there were no oxidation of alcohol within the body. No matter what concentration of alcohol is breathed absorption continues at a fairly constant rate over an extended period because the total amount of alcohol that can be supplied to the blood by way of the lungs is much lower than the amount of this substance that the blood and tissue can dissolve. A different situation exists with a relatively insoluble vapor such as ether which has a distribution coefficient

between air and blood of 14.9.⁴ According to the figures given by Haggard⁵ only sixty to one hundred and twenty minutes are required to saturate the body of a dog with ether when the vapor is present in a concentration of about 3 per cent by volume (30,000 parts per million). This means that less and less ether is absorbed with each succeeding breath and with each additional circuit of the blood through the body, until there is no further retention. The saturation point is then reached.

The elimination of a solvent vapor depends on several factors most important of which are the solubility coefficient between blood and air and the amount of body oxidation and metabolism of the vapor. It has been proved² that the higher the solubility of a vapor the less rapidly is an organism desaturated after termination of the exposure and the lower the solubility of the solvent vapor the more rapidly is the organism desaturated. With alcohol the rate of removal by the lungs is slow, and were it not for a rapid rate of oxidation the desaturation rate following exposure to this substance would be extremely slow. With ether⁴ approximately 90 per cent is excreted in the expired air at a relatively rapid rate and only small amounts are excreted in the urine and sweat. None of the ether is metabolized.

In a recent paper one of us⁶ showed that carbon disulfide is relatively insoluble with a low blood-air coefficient of distribution of 2 to 3. In the same paper the rate of absorption of carbon disulfide in dogs and the rate of elimination of the substance following cessation of exposure were found to be rapid. Experiments reported in the present paper confirm these observations on dogs and show similar rapid rates of absorption and elimination of carbon disulfide in man. Unlike ether carbon disulfide is not excreted mainly by the lungs. Only 8 to 13 per cent is expired, about 0.5 per cent is excreted in the urine and none in the feces. The remaining 85 to 90 per cent is metabolized, largely by oxidation and by combination.

In the experiments to be reported in this paper, some insight has been obtained into the mechanism of the action of carbon disulfide. It is well known from the extensive literature on the subject and from Dr. Alice Hamilton's review⁷ that carbon disulfide absorbed in appreciable concentrations over a long period of time may result in damage to nerve tissue. Recent work by Lewey⁸ indicated that vitamin B₁ may play some role in protecting against the action of carbon disulfide. In the study of a number of isolated enzyme systems essential for carbohydrate metabolism and therefore, concerned with proper nerve function we have found only the succinic-oxidase system to be partially inhibited by carbon disulfide.

RATE OF ABSORPTION AND ELIMINATION OF
CARBON DISULFIDE

The rate of absorption and elimination of carbon disulfide was studied in 12 dogs and 5 men. The dogs were at rest during both saturation and desaturation.

From the Harvard School of Public Health.

This study was made possible by a grant from the American Viscose Corporation, Wilmington, Del. Miss Ellen Marston gave the authors technical assistance.

The major part of the material in this paper was read before the American Industrial Hygiene Association, Pittsburgh in May 1941 and before the New England Industrial Hygiene Association, Boston in November 1941.

¹ The coefficient of distribution for a vapor is a ratio of the amount of vapor at equilibrium which is distributed between a vapor air phase and an immiscible phase, for example the vapor distribution between blood and air. This ratio $\frac{\text{amount of vapor per unit volume of blood}}{\text{amount of vapor per unit volume of air}}$ is expressed as a whole number.

while the men were at rest during saturation and were carrying on their normal laboratory work during desaturation. Carbon disulfide vapor of known concentrations was inhaled by the experimental subjects until the blood became saturated, as shown by periodic sampling and analysis. Exposure to the vapor was then

Chart 1—Arterial blood saturation and desaturation and urinary excretion of carbon disulfide. Dog 2 exposed to carbon disulfide vapor (50 parts per million) for three and one half hours.

terminated and the level of carbon disulfide in the blood followed periodically until analyses showed that little or none was present.

Experiments on Dogs—All dogs employed in these experiments were anesthetized with soluble pentobarbital, and isotonic solution of sodium chloride (20 cc per kilogram of body weight) was given intravenously. Following this, the trachea was cannulated and artificial respiration begun by connecting the trachea cannula with a respiration pump. The left femoral artery and vein were cannulated for recording of blood pressure and blood sampling.

In order to study quantitative elimination of carbon disulfide—a subject which will be discussed later—the urethra was tied off and the bladder was cannulated with a specially designed, glass stoppered cannula so that urine unexposed to air could be withdrawn at any time. This glass cannula had a stem 5 cm long and 3 mm in diameter and a ground-glass stopper. The lower end widened into a bulb 1 cm in diameter with five 1 mm openings to allow rapid filling from the bladder.

In each experiment a thirty minute control period for recording of blood pressure and respiration rate was taken. The bladder was emptied and control blood samples were taken. The carbon disulfide exposure was

Chart 2—Arterial blood saturation and desaturation and urinary excretion of carbon disulfide. Dog 6 exposed to carbon disulfide vapor (25 parts per million) for two and one half hours.

then started by connecting the trachea cannula to the respiration pump and thence to the source of vapor. With the last 4 dogs studied, the pump was not used and the animals maintained a normal respiratory rate. The results are similar to those on animals maintained with the pump. Not in any case was there a noticeable change in blood pressure, heart rate, respiratory rate, respiratory volume or body temperature during the entire experiment. The values were all normal.

The carbon disulfide vapor was generated at a constant rate by a vapor generator described in a previous

paper.⁹ The constancy of the vapor concentration, as determined by analysis every thirty minutes, was within ± 1 part per million of an acceptable figure. The vapor was blown into an air-tight metal mixing reservoir with an outlet tube to allow the escape of excess vapor. Neoprene tubing ($\frac{5}{8}$ inch in diameter) was used to connect the vapor reservoir, the respiration pump and the inhalation trachea valve. The exhalation trachea valve used for the last 4 dogs was connected with $\frac{1}{8}$ inch neoprene tubing to two calibrated spirometers connected in parallel. The trachea valves were connected as closely as possible to the trachea cannula, so that the dead space was about the same as in the intact animal. The valves used were a hinged flap type and all-metal construction to prevent absorption of carbon disulfide.

The blood carbon disulfide level was followed by analysis of blood samples collected every thirty to sixty minutes.¹⁰ Arterial blood (10 cc) was taken from the femoral artery cannula and venous blood (10 cc) taken directly from the femoral vein by means of 10 cc calibrated syringes. As indicated previously, when the blood carbon disulfide level became constant, exposure was stopped. Blood sampling was then continued until only a negligible amount of carbon disulfide remained in the blood.

Charts 1, 2 and 3, which are representative of all 12 dogs studied, show that blood saturation was reached

Chart 3—Venous and arterial blood saturation and desaturation. Dog 3 exposed to carbon disulfide vapor (40 parts per million) for one and one half hours.

within thirty to one hundred and twenty minutes. Occasional venous blood analyses (chart 3) showed, at the cessation of exposure, a condition close to tissue saturation. As would be expected from the limited capacity of the lungs to supply

vapor to the blood, the higher concentrations of vapor required somewhat longer periods to attain saturation.

The major part of desaturation took place within thirty to sixty minutes (charts 1, 2 and 3) and at a slightly faster rate than saturation; however, the removal of final traces of carbon disulfide required an additional two to six hours (table 1). This time, as would be expected from a theoretical consideration, was usually somewhat longer with the higher exposure concentrations. There was, however, apparently no prolongation of the desaturation time with the longer exposures. This is to be expected from the fact that only small amounts of a solvent are absorbed after the saturation point is reached.

Human Experiments—Studies similar to those on dogs were made on 5 normal men. Exposures necessarily were at a lower concentration for men than for dogs. None of the subjects noticed any immediate or belated effects from the vapor exposures. In each case, the blood pressure, heart rate and respiratory rate were all normal throughout the experiment. Generation of vapor was effected in the same way as in the experi-

ments on dogs Neoprene tubing (1 inch in diameter) was connected to the vapor reservoir with the subject's metal inspiratory valve and plastic face mask. The same type of tubing connected the mask and metal outlet valve to a gas meter for measuring the respiratory volume. Samples of expired air were taken at intervals to show the course of carbon disulfide removal in the expired air, and these corresponded well with blood values. Only venous blood was examined.

With the men as with the dogs blood saturation was reached rapidly (sixty to ninety minutes) after which only a small amount of carbon disulfide was absorbed and that only as the carbon disulfide was metabolized and excreted. At the termination of exposure there was rapid desaturation for the first sixty minutes. Desaturation as shown by urine and expired air values,

* Time after exposure was stopped

was complete after three to eight hours. Charts 4 and 5 are representative of all 5 subjects while critical data for all 5 are shown in table 2.

In a number of other human experiments not shown in this paper, the rates of saturation and desaturation were somewhat increased by exercise. This of course does not affect the saturation level—only the rate at which it is attained.

TOTAL AMOUNT OF CARBON DISULFIDE ABSORBED AND ELIMINATED

Although the dog and human saturation and desaturation curves show the rates of absorption and elimination they do not show the quantities of carbon disulfide which were handled. In order to arrive at a quantitative estimation of the amounts involved the following four determinations were made:

1. Concentration of vapor breathed
2. Carbon disulfide in the total expired air during saturation
3. Carbon disulfide in the total expired air during desaturation
4. Total carbon disulfide in the urine

By calculation, it was then possible to determine the amount of carbon disulfide retained during the exposure period and the amount eliminated by way of the expired air during desaturation. By the collection and analysis of urine the amount excreted by that pathway was determined.

Chart 4—Venous blood saturation and desaturation and urinary excretion of carbon disulfide. Human subject 37 exposed to carbon disulfide vapor (22 parts per million) for one and one half hours.

Experiments on Dogs—In order to collect the total volume of expired air over the extended period of the experiments two spirometers were connected in parallel. This arrangement permitted the analysis and emptying of the contents of one spirometer while the second was being filled. The spirometers were calibrated for dead space and water solubility with known concentrations of carbon disulfide vapor.

In all cases expired air was collected until no more carbon disulfide was found to be present. Samples of the urine were removed from the bladder through the glass stoppered cannula by means of a syringe and long needle.

Table 4 shows the determined and calculated results for the saturation and desaturation periods. The data presented include length of exposure, exposure concentration of vapor, amount of carbon disulfide inspired, amount of carbon disulfide retained, percentage retained, length of time for desaturation, amount of carbon disul-

Chart 5—Venous blood saturation and desaturation and urinary excretion of carbon disulfide. Human subject 38 exposed to carbon disulfide vapor (2 parts per million) for two hours.

hide removed in expired air and percentage removed of that retained. It is of interest to note that only 8 to 13 per cent of the retained carbon disulfide is removed in the expired air. It is of interest also that the carbon disulfide excreted in the urine is only about 0.5 per cent of the total amount retained (table 1).

Human Experiments—The large volume of air breathed by a man during the relatively long time required to saturate his blood with carbon disulfide and then desaturate it made long exposure periods impractical. Shorter exposure periods were however, studied by a procedure similar to that used in the experiments on dogs. The results as shown in table 3 indicate that 6 to 10 per cent of the retained carbon disulfide is given off in the expired air—percentages which are similar to those obtained in the experiments on dogs. It will be noted from the figures in table 3 that as the exposure time was increased and the body became more nearly saturated the retention percentage decreased, also, following the termination of exposure the percentage excreted in the expired air was increased.

The total amounts of carbon disulfide present in the urine of the 5 human subjects during the saturation and desaturation periods accounted for only about 0.5 per cent of the retained carbon disulfide (table 2).

METABOLISM OF CARBON DISULFIDE COMBINATION AND OXIDATION

It has been demonstrated that 8 to 13 per cent of the retained carbon disulfide is excreted in the expired air and that less than 1 per cent appears in the urine. The next logical question to be asked concerning carbon disulfide excretion is: What happens to the remaining 85 to 90 per cent of the retained carbon disulfide? Obviously the question of excretion in the feces and sweat must be considered. Human fecal material collected for twenty-four hours during and following vapor exposure, yielded no carbon disulfide on analysis. Although absorption and elimination by the skin were not studied, we believe that little carbon disulfide would be removed by way of the sweat because of the low solubility of carbon disulfide in aqueous fluids. It is therefore clear that the 85 to 90 per cent of retained carbon disulfide which is unaccounted for must be metabolized in some manner.

It should be remembered that in the estimation of carbon disulfide in urine and feces only volatile carbon disulfide is determined. Hence any nonvolatile com-

attempt to ascertain whether there was any increase in sulfur metabolites during and following exposure to carbon disulfide.

Human Studies—In order to maintain the urinary sulfates as constant as possible, the subject went for five days on a diet of constant protein, fat and carbohydrate.

intake. Special note was taken of the protein, since it is this dietary constituent principally which influences the urinary sulfates. The total urine output was collected in six to twelve hour samples, and duplicate analyses were made by Fiske's modification of the Roscolium and Drummond method¹¹ for inorganic sulfate, sulfur, total sulfate, sulfur and total sulfur. Similar analyses were made on aqueous extracts of feces collected for twenty-four hours during and following exposure to carbon disulfide. After two days on the constant diet the subject was exposed for six hours in a vapor chamber to carbon disulfide (25 parts per million).

As shown in table 5 there was some increase both in the inorganic sulfates of urine and in the total sulfur. The fact that the total sulfur increase was about the same as the inorganic sulfate increase indicates that there was an increase only in the urinary inorganic sulfates. Whether or not this increase accounts for the remainder of the retained carbon disulfide cannot be stated with accuracy. Calculated on the basis of body saturation being reached for 25 parts per million in sixty minutes and based on a 40 per cent retention during the period (table 4), the increased sulfur in the urine during exposure and for twenty-four hours following exposure accounts for about 90 per cent of the retained carbon disulfide.

Fecal analyses showed no increase above normal for any of the three sulfur constituents.

Studies on Rabbits—Metabolism experiments, similar to those cited, were conducted on 2 rabbits. One rabbit was injected with 2 cc of carbon disulfide in vegetable oil, while the other was exposed to carbon disulfide (2,000 parts per million) for sixty minutes.

As shown in table 6, in both animals there was a decided increase of urinary inorganic sulfates and total sulfur, and the latter increase was more than the inorganic sulfate increase. This means that some carbon disulfide combination product, an organic compound was also being excreted in the urine. This we believe is probably a combination product of carbon disulfide with an amine or ammonia in the blood stream or in the body tissues.

In these rabbit experiments it was even more difficult than in the ones on human beings to determine whether

bination compound or oxidation product would not be detected. It was this type of metabolite that we next considered in studying the elimination of carbon disulfide, namely possible combination products of carbon disulfide with amines and ammonia and/or carbon disulfide oxidation to sulfuric acid and excretion as inorganic sulfates.

Both urine and fecal materials were analyzed for inorganic sulfates, total sulfates and total sulfur in an

or not all the retained carbon disulfide was accounted for. This was especially true of the injected animal because we do not know how much carbon disulfide was excreted in the expired air.

A calculation similar to the one used in the human experiments indicated that only about 25 per cent of the retained carbon disulfide was metabolized during the twenty-four hours following exposure. This would be expected from the exceedingly high concentration administered and the logical conclusion that there is a limit to the mechanisms of detoxification in the animal body.

The important fact is that there are probably at least two mechanisms for detoxifying carbon disulfide, i.e., oxidation and combination.

It is important to point out here that the actual amount (in milligrams) of carbon disulfide retained during a day's exposure is quite small even with the higher concentration studied in the animals. For this reason it is extremely difficult to follow accurately the metabolites excreted in a fairly large volume of urine over a number of hours. Studies with carbon disulfide containing radioactive sulfur are being considered in an effort to determine quantitatively the carbon disulfide metabolized and the rate of metabolic excretion.

MODE OF ACTION OF CARBON DISULFIDE

The belief in the past has been that the toxic effects of carbon disulfide are due largely to its solvent action on the lipids of the nervous system. The fact that nerve tissues may be damaged at relatively low concentrations of carbon disulfide (a few tenths of a milligram per kilogram of tissue) indicates that something other than a solvent action is responsible. We have

attempted to obtain an insight into the mechanism of action of carbon disulfide by a systematic survey of the effect of carbon disulfide on various known types of enzyme systems in the animal body. Warburg manometric experiments on isolated tissue enzyme systems indicate that at least one system important in carbohydrate oxidation is somewhat impaired. Inhibition of such systems is of paramount importance and may help to explain the nervous syndromes produced by carbon

disulfide, because nerve tissue depends on energy derived from carbohydrate metabolism.

Among the systems studied at the present time the succinic oxidase enzyme system is the one most inhibited, showing a 10 per cent decrease in activity when a carbon disulfide concentration of 0.005 molar has been

TABLE 6—Sulfur Content of Rabbit Urine Following Exposure to Carbon Disulfide

reached. This inhibition may be a possible explanation for the action of carbon disulfide on nerve tissue. The systems in which vitamin B₁ functions—pyruvic acid oxidase and pyruvic acid decarboxylase, also lactic acid dehydrogenase—were not inhibited by concentrations of carbon disulfide as large as 0.007 molar. These isolated enzymes studied are being extended to *in vivo* experiments (laboratory animals and human beings).

COMMENT

The uses of solvents in present day industry are rapidly increasing and extending to new types of compounds. With this increase in the utilization of solvents there arises the necessity for a broader understanding of control methods and therapeutic measures in order to prevent the occurrence of damage to the worker absorbing toxic vapors in untoward quantities. Such an understanding involves a detailed knowledge of the medical aspects of the physiologic action of solvent vapors. In this paper we have considered some of the more important of these problems for carbon disulfide and have indicated possible approaches for the study of other volatile solvents. As stated previously, these are (1) the rate and extent of absorption into the individual's body, (2) the rate of excretion, (3) the rate and the amount of the compound metabolized by the body, (4) the site of action of the vapor and (5) the manner in which the toxic action is elicited.

A study of the rate of vapor absorption is important because it makes possible a determination of the amount obtained during the exposure time of a working day or the dose with which one has to cope. Admittedly small quantities of certain vapors are absorbed by way of the skin, however the major portion of most vapors enters the blood by way of the alveoli from the inspired air.

The rate of elimination is an aid in determining the length of time that the compound remains in the body and therefore a measure of the time that the compound may act on the organism. In regard to these two aspects the solubility of the vapor in water and lipids is of extreme importance. Thus a water insoluble compound like carbon disulfide rapidly saturates the body, which is about 70 to 75 per cent water and ceases to be absorbed except as excretion and metabolism progress. On the other hand a water soluble compound for instance ethyl alcohol requires manifoldly greater quantities of the vapor and correspondingly longer periods of time to saturate the body.

Metabolism of a solvent vapor is a further important consideration, since it furnishes another pathway for removal of the noxious material from the body, thus facilitating excretion. There is, in addition, the possibility that the metabolic products may be less toxic than the original vapor.

Consideration of the mode of action of the toxic material is of paramount importance, since it will indicate the site of action and mechanism of reaction, which may in turn lead to the discovery of preventive and therapeutic measures.

SUMMARY AND CONCLUSIONS

Laboratory animal human and in vivo tissue experiments on the absorption, elimination, metabolism and mode of action of carbon disulfide show the following results:

1 Saturation of the body with the relatively insoluble solvent vapor of carbon disulfide is quite rapid, requiring from thirty to sixty minutes. The necessary time interval depends largely on the exposure concentration and is longer with higher concentrations.

2 The major part of the elimination of retained free carbon disulfide takes place in the first thirty minutes, complete desaturation however requires three to eight hours. The rate of desaturation like the rate of saturation depends to a large degree on the exposure concentration, a longer time being required with a higher concentration.

3 No matter how high the exposure concentration, a saturation point is reached beyond which there is no further absorption of carbon disulfide except as it is metabolized and excreted in the urine.

4 Of the retained vapor, about 8 to 13 per cent is excreted in the expired air, about 0.5 per cent in the urine and none in the feces.

5 The remaining 85 to 90 per cent of carbon disulfide is probably accounted for as metabolites (inorganic sulfates and organic sulfur compounds) excreted in the urine.

6 No free or metabolized carbon disulfide is found in the feces.

7 In vitro manometric experiments show that carbon disulfide in relatively large quantities inhibits slightly the succinic oxidase enzyme system, important in intermediate carbohydrate oxidation and normal nerve tissue metabolism. The pyruvic acid oxidase, pyruvic acid decarboxylase and lactic acid dehydrogenase systems which involve vitamin B₁ were not inhibited by carbon disulfide.

Indigestion of Old Age—One of the rules with regard to indigestion in old age is to reduce the diet gradually. If an active sedentary man consumes 2,400 to 3,000 calories a day, a person 55 to 65 should be able to get along on 1,800 to 2,000 calories a day. I have repeatedly attempted to determine the calory intake of certain people, even octogenarians, and I learned that many of them consumed 2,400 calories or more and only do so because they seem to have intact eliminatory organs. We are inclined to look at old age as a progressive disorder resulting in gradual thickening of the vessels and loss of the cardiac reserve. Many of these people show evidence of kidney damage by gradual failure in urinary concentration with nocturia as a result—Rehfuss, Martin E. *Indigestion Its Diagnosis and Management*, Philadelphia, W. B. Saunders Company, 1943.

DEMEROL—A NEW SYNTHETIC ANALGESIC

A REVIEW OF ITS PRESENT STATUS AND COMPARISON WITH MORPHINE

ROBERT C. BATTERMAN, M.D.
NEW YORK

AND
C. K. HIMMELSBACH, M.D.
Surgeon, United States Public Health Service
WASHINGTON, D.C.

The increased need for morphine in time of war and the present threat to our opium supply make it important that appropriate consideration be given to the new analgesic Demerol, for this compound can be prepared synthetically from available chemicals. Although it has been used in this country by only a few investigators and only recently was released by the Food and Drug Administration, considerable knowledge has accumulated concerning its pharmacology and clinical usefulness. It is therefore considered advisable to present at this time a review of present knowledge on Demerol with especial reference to its pharmacology, clinical uses and safety in comparison with morphine.

Demerol (1-methyl 4-phenyl-piperidine 4-carboxylic acid ethyl ester hydrochloride) was synthesized in 1939

Demerol

Atropine

by Eisleb and Schaumann.¹ It represents one of a large group of piperidine compounds possessing spasmolytic properties. Its close similarity to atropine can be discerned on inspection of the chemical formulas.

It is therefore not surprising that Demerol possesses mild atropine-like properties. Of greater interest, however, was the unexpected finding that the drug had a morphine-like effect on the central nervous system of animals. Definite analgesia comparable to that of morphine without the occurrence of a striking depression of the central nervous system has been reported.² While close chemical similarity of morphine and Demerol is difficult to visualize in a flat plane, it is possible with molecular models to discern similarities involving particularly the piperidine ring.

THREE ACTIONS OF DEMEROL

Demerol possesses three main actions: analgesia, spasmolysis and sedation. The relative analgesic effect as compared with codeine and morphine can be demonstrated by the method of Hardy, Wolff and Goodell.³

From the Department of Therapeutics, New York University College of Medicine.

³ Hardy, J. D., Wolff, H. G., and Goodell, H. Studies on Pain: A New Method for Measuring Pain Threshold. *Observations on Spatial Summation of Pain*, *J. Clin. Investigation* 19: 649 (July) 1940.

The administration of 100 mg of Demerol orally results in an elevation of the peripheral pain threshold within fifteen minutes reaches a peak of approximately 50 per cent at the end of one hour and gradually subsides in about six hours.⁴ Intramuscularly the effect appears within ten minutes, reaches its peak in forty-five minutes and persists for several hours. By this method 50 mg of Demerol intramuscularly was found⁴ to be approximately twice as potent as 22 mg of codeine. Similarly, 125 mg of Demerol approaches the effectiveness of 17 mg of morphine but does not persist as long.

The practical use of this effect in man has been applied to the relief of pain due to a large variety of conditions.⁵ The duration of analgesia is about three hours. Visceral pain such as that arising from the peritoneum, pleura or smooth muscle is relieved more effectively than pain arising from skeletal and neurologic structures. Data on the comparative analgesic effectiveness of Demerol and morphine are given in table 1.

Demerol administered parenterally is at least as effective as morphine in producing clinical analgesia. Comparative studies⁶ on the same patient would indicate that 100 mg of Demerol parenterally is equivalent to 10 mg of morphine. This observation is likewise borne out from the data presented in table 1. Oral administration of Demerol is less satisfactory than parenteral administration, perhaps because of variations in absorption. The incidence of side reactions is higher in ambulatory patients who receive the medication by mouth. Nevertheless the oral route is useful and yields satisfactory results.

In postoperative patients, Batterman and Mulholland⁷ have reported that Demerol is a more suitable drug than morphine or its derivatives. The reasons for this will become evident as the pharmacology of the drug is discussed. The value of Demerol in surgical conditions has been reported also by other investigators.⁸ Satisfactory use of Demerol for analgesia in obstetric patients has been found by Benthin,⁹ Gilbert and Dixon,¹⁰ Son-

nek,¹¹ Roby and Schumann¹² and Studdiford and Batterman.¹³

The second important action of Demerol is its general spasmolytic effect in man. Intubation studies¹⁴ have demonstrated this action on the stomach, pylorus and small and large intestine of human subjects. The effect is due to an atropine-like action on the parasympathetic nerve endings and a papaverine-like direct depression of smooth muscle.¹⁴ In direct contrast to the action of opiates the motility of the intestine is so influenced that the segmental contractions and tone are diminished or abolished while propulsive action is unaltered. Clinically this action is manifested by the rapid and often dramatic relief of colicky pain. Prolonged use of the drug in therapeutic doses does not result in constipation. Hence Demerol is of little value in the treatment of diarrhea and cannot replace opiates for this purpose. Thus it would appear that Demerol has definite spasmolytic action in man.

Experiments however, on the gastrointestinal tract of animals have yielded variable results, depending on the segment (whether isolated or in situ) the species of

TABLE 1—Comparative Analgesic Effectiveness of Demerol and Morphine

Medication	Route	Number of Patients	Number of Doses	Average Dose, Mg	Adequate Analgesia per Cent	Slight or No Analgesia per Cent
Morphine Lee L E Jr J Pharmacol & Exper Therap 75 161 (June) 1942	Subcutaneous	776	4,571	9.6	96.7	3.3
Demerol Batterman ⁶	Subcutaneous	831	10,320	100	99.8	4.2

Demerol Batterman	Oral	604	10,951	50.100	84.3	15.7

animal used and the method of study. These have been summarized in table 2.

In contrast to the effect of morphine an antispasmodic response on the intact ureter by Demerol has been demonstrated in animals and man by Chimenko and Berg.¹⁵ The relief to patients with renal and ureteral colic is thus explained by experimental evidence.

Studies on intact and excised uteri revealed relaxation¹⁶ but this was refuted by Gruber and his associates¹⁷ and by Yonkman.¹⁸ The administration of Demerol in doses of 100 to 400 mg over a period of two to four hours to pregnant women neither altered the rhythmic contractions nor delayed labor.¹¹ On direct studies of the pregnant human uterus with a balloon Woodbury and his associates¹⁹ found no effect on uterine contractions.

An antispasmodic effect on bronchial musculature was noted in animal experiments by Schaumann,² Gruber¹⁷ and Barlow.⁴ Clinically beneficial effects in patients with bronchial asthma have been reported by several investigators.¹¹ It is well known that the use of morphine is contraindicated for such patients. Ambulatory asthmatic patients have fewer and less severe attacks when Demerol is administered every four hours. An acute attack of asthma can be relieved within ten minutes by the subcutaneous injection of 35 mg. a dose far below that required to produce analgesia or sedation. The bronchial relaxation is less than that achieved with epinephrine. Nevertheless Demerol probably has a theoretical advantage as an antiasthmatic agent, since it would tend to reduce the autonomic reactions usually associated with a severe attack. Epinephrine would heighten the fear component even though the asthma was relieved. Good results have been obtained with a

generally free from untoward reactions of this character. Because intravenous administration results in a sharp fall in blood pressure, the drug should never be given by this route. Direct cardiac depression does not occur with therapeutic doses, and the normal electrocardiogram is unaltered. The third action of Demerol to be considered is sedation. This usually occurs with the larger parenteral doses, resulting in sleep from which the subject can be aroused easily. It usually subsides within two hours, but when the drug is given at night or to patients who have been sleepless because of pain the sleep may last longer. Patients note no after-reactions or mental confusion on awakening. Ambulatory patients may complain of drowsiness at first, but tolerance is developed to the sedative effect. Like morphine, Demerol in animals potentiates the hypnotic effect of evipal soluble,²⁵ shortens the induction

mixture consisting of 35 mg. of Demerol and half the usual amount of epinephrine.²² The vasodilating properties of the drug are transitory. In animals Demerol produces a fall in blood pressure,²³ an increase in volume of the limb and spleen¹⁷ and an increase in blood flow.²⁴ In man, demonstrable alterations of the circulation are not pronounced except in hypersensitive persons in the upright position. Thus approximately 5 per cent of ambulatory patients may experience syncope, a fall in blood pressure, bradycardia and signs and symptoms of shock suggestive of generalized vasodilatation and inability to maintain the circulation ("nitritoid" reaction). These usually subside quickly when the supine position is assumed. The administration of the drug to recumbent subjects is

time and prolongs the anesthetic time of a given amount of nitrous oxide-oxygen.⁴ Rovenstine and Batterman²¹ reported on the ability of Demerol to reduce the amount of inhalation agent required to secure a certain degree of anesthesia in dogs and to prolong the effect of pentothal sodium. In a series of 338 surgical patients requiring a general or spinal anesthetic Demerol was found²⁶ to be in every way as satisfactory a pre-anesthetic agent as morphine. With the exception of hypersensitive persons, particularly those with advanced cerebral arteriosclerosis, respiratory depression is not usual with the use of Demerol. In animals, however, transitory respiratory depression has been reported by all investigators,²³ and large intravenous doses may result in death by respiratory paralysis. It is of interest to note that in man Demerol has little if any sedative

25 Barlow, O. W., Chimenko, D. R., and Homburger, E. Comparative Potentiating Effects of Certain Therapeutic Agents on Sodium Evipal Hypnosis, Proc. Soc. Exper. Biol. & Med. 49: 11 (Jan.) 1942.

effect on cough although because of its atropine-like action in occasional patient may be benefited by its decreasing the bronchial secretions

Other pharmacologic studies reveal no effect on the size of the pupil or ocular accommodation in man. Corneal anesthesia may occur. The basal metabolic rate is unaltered. Dryness of the mouth, flushing of the face and perspiration are common findings. Dizziness occurs as the most frequent untoward reaction. Nausea and vomiting are noted less frequently than with morphine.

TOLERANCE

The treatment of chronic intractable pain raises three important questions: 1. How often and in what dosage may Demerol be administered without the danger of cumulation of toxic effects? 2. Will tolerance result from prolonged administration? 3. Will prolonged use of the drug result in addiction?

Moderately intense pain can be controlled with 50 to 100 mg orally or parenterally every four hours. With severe pain as much as 150 to 200 mg has been given every three hours without observed harmful effect. It is rarely necessary to exceed this dose to achieve satisfactory relief of pain. Furthermore if this dose is unsatisfactory it is unlikely that greater relief will be obtained by the use of more Demerol or comparable doses of morphine.

Himmelsbach² and Andrews²⁸ reported that former addicts receiving 200 to 300 mg every one and one-half to two hours may have severe muscular tremors and occasional epileptiform seizures. Severe reactions of this caliber have not been noted with the clinical use of the drug. Occasional "jumpy" feelings, muscular twitches or tremors of uncoordinated character occur in 0.4 per cent of hospitalized and 5 per cent of ambulatory patients.⁶ Duguid and Heathcote,²⁹ Barlow⁴ and Schumann² have each reported the weak cerebral depressant action of Demerol in animals with amounts comparable to therapeutic doses but cerebral stimulation and convulsions with larger doses. With therapeutic doses Demerol does not result in progressive depression of the central nervous system such as may be seen with frequent and repeated doses of morphine in nontolerant patients. On the other hand excessive doses may result in cerebral irritability.

Prolonged use of Demerol in animals and man has not resulted in alteration of the hemopoietic system or produced disturbances in liver or kidney function. Urinary retention is rare. To date no disease or other medication has been found incompatible with Demerol.

Demerol is rapidly destroyed by the liver.⁴ The nature of the breakdown products is not clear, but it has been suggested that the first step is hydrolysis of the ester group. Pharmacologic studies on such a compound revealed no typical Demerol effects. The rapidity of destruction of the drug in vivo may account for the relatively short period of analgesia, the small amounts of the drug detectable in the urine³⁰ and the ability to administer the drug for prolonged periods at intervals of three to four hours without cumulation of toxicity.

Any discussion of tolerance must take into account the various effects that can be produced with Demerol. Repeated doses of opiates result in the development of tolerance to the depressant effects on the central nervous system such as sedation, analgesia and respiratory depression. Evidence for the development of tolerance in former addicts to the pain threshold raising effect of opiates and Demerol has been furnished by Andrews.³¹ In the case of Demerol, tolerance to the skin pain threshold raising effect is usually manifest within two weeks and reaches a maximum at the end of eight weeks. In a group of 115 hospitalized patients³² receiving from 42 to 492 doses of Demerol within periods of from four to twenty-eight weeks no appreciable tolerance to its general clinical analgesic effect occurred. Clinical analgesia is probably the result of one or more of the following effects: (1) a central action on the midbrain or the thalamic area blocking or reducing the transmission of pain sensation from the periphery to the cerebral cortex; (2) an altered reactivity of the patient to the pain so that even if perceived the "fear reaction" is not evoked and (3) an increased threshold to painful stimuli at the periphery. The latter factor, although of immense help in evaluating relative potency of analgesics appears to be of minor importance as far as general analgesia is concerned.

In addition to the peripheral pain threshold raising effect, tolerance develops rapidly to the somnolent action and to many of the side actions.

ADDICTION

With any drug possessing morphine-like action on the central nervous system serious consideration must be given to questions concerning the possibility of addiction. In the pain free, normal experimental subject, the effects of Demerol are described variously, depending perhaps on the underlying psychologic makeup of the individual. To some it is pleasant like a cocktail" or the development of a sense of well-being while in others there is an ill defined, disagreeable sense of insecurity or the occurrence of unpleasant dreams. These sensations are neither consistent nor predictable. Some subjects like the effect and want to repeat it, while in others the converse attitude occurs. Since this may involve the 'nitritoid' reaction the position of the patient may influence the effect and subsequent use of the drug. The implications of the experience and the personality makeup of the individual are obvious.

Drug addiction is a condition in which a person has lost the power of self control with reference to a drug. When a regularly pleasant effect leads to a strong desire for its frequent repetition, psychic dependence or habituation is apt to result. An extension of such frequent and regular repetition of a drug as regards both dosage and interval of administration may lead to the development of physical dependence. Physical dependence, a serious consequence of opiate abuse is perhaps related to overcompensation by the autonomic nervous system in order to maintain homeostasis of certain vital functions disturbed by the drug. On discontinuation of the drug an abstinence syndrome consisting of characteristic signs and symptoms occurs.³³ While physical

dependence on Demerol has not yet been encountered in "normal" persons it has been produced in former addicts.³⁴ However, because of the brief duration of the physical dependence action of Demerol and its lesser potency than morphine in this regard the experimental production of physical dependence on Demerol is not easy even for such patients. For example, habituation but no significant physical dependence resulted from the administration of 75 mg. of Demerol four times a day for a period of three months. Nor did clinically significant physical dependence develop when the drug was administered in amounts of 75 to 100 mg. eight times a day for four weeks to former addicts who had never before received Demerol. However, those who had had previous experience with Demerol developed definite physical dependence to the latter dosage after two weeks of readministration. On the other hand when Demerol was clinically readministered to patients who were not former addicts, abstinence phenomena were not encountered on its subsequent discontinuation. While the implication of these results is not yet clear they suggest that a somewhat different mechanism may be involved than that entailed in the development of physical dependence to morphine.

It would seem therefore that questions concerning the development of physical dependence on Demerol must be considered from the following points of view:

1. Can Demerol produce physical dependence? The answer to this is yes.

2. Is physical dependence likely to result from the bona fide use of Demerol in the practice of medicine? This has not been encountered nor do we feel that it is likely to be if the therapeutic requirement is not exceeded. On the other hand it is not uncommon to note the development of physical dependence on opiates by patients requiring their use for a chronic ailment. Such patients are not usually considered addicts in the sense that abuse of the drug is not an outstanding feature. Nevertheless it is often difficult to distinguish between the actual necessity for morphine to alleviate the condition or satisfy the physical dependence. This experience agrees with the theoretical relationship³⁴ to the development of physical dependence of the relative potencies and the durations of action of morphine and of Demerol the latter being weaker and shorter in its physical dependence action.

3. Under what conditions may physical dependence to Demerol be expected? (a) In an unstable person who otherwise would abuse an opiate to the point of addiction but who had had no previous opiate experience? While this is a very important question it cannot be answered at the present time, since the drug has been available to this type of person for an insufficient period of time.

(b) In an unstable person suffering an illness requiring prolonged administration of a potent analgesic who will seek the drug subsequent to discharge not for continued therapeutic effects, but because it satisfies his inebriate impulse? Again, we do not know, for the same reason.

(c) In an otherwise normal person suffering an illness requiring the prolonged administration of a potent

analgesic? To date it has been possible to study this question by withholding the drug from 47 of 115 patients³⁵ who had received it for long periods of time. In none of these patients were signs or symptoms of abstinence encountered.

(d) In a former morphine addict? If Demerol is abused by such a person, physical dependence is apt to result. It is not yet known whether the therapeutic use of Demerol for the relief of chronic painful conditions in former addicts is liable to result in physical dependence. Results of its chronic administration in therapeutic doses to pain-free former addicts suggest that it may be safer than morphine in this regard.

The ability of Demerol to produce physical dependence among former morphine addicts raises the question of whether or not the drug is of any value in the treatment of the morphine abstinence syndrome. Although it is conceded that the best drug for this purpose is morphine itself, Demerol also definitely modifies the syndrome and can be used satisfactorily in place of morphine for this purpose.³⁵ Its ameliorative action is considerably briefer than that of morphine and this must be taken into account in prescribing a rapid reduction treatment with the drug. Large frequent doses are required when patients are being treated who have shown a strong dependence on morphine. For such patients Demerol is not only less satisfactory than morphine but may result in undesirable side actions including toxic psychosis. With patients who have less intense physical dependence, Demerol is a satisfactory drug in the treatment of the morphine abstinence syndrome. It must be emphasized, however, that if Demerol is continued in the treatment of such patients, physical dependence may be shifted from morphine to this drug. Hence it is necessary to reduce the dose progressively. Furthermore, "breaking the habit" in an individual case while under observation does not constitute a "cure" since the psychiatric makeup of the patient remains unaltered and unless corrected drugs are resorted to again on discharge.

CONCLUSION

With the exception of the production of cough and diarrhea, Demerol has been found to be a satisfactory therapeutic substitute for morphine. It appears to possess the following clinical advantages over morphine:

1. Its spasmolytic action makes it ideal for the relief of conditions due to smooth muscle spasm in which morphine is pharmacologically contraindicated.

2. Its rapid dissipation tends to offset undesirable cumulative effects such as respiratory depression and urinary retention.

3. Prolonged use of Demerol may lead to the development of habituation but it appears to possess a lesser liability than morphine for the development of physical dependence.

In order to avoid the dangers of habituation, physical dependence and undue cerebral irritability amounts greater than 150 mg. every three hours should not be given. We wish to reemphasize the point that if this amount will not meet the clinical need, increasing the dose and shortening the interval not only may not have any additional therapeutic value but is apt to result in serious consequences.

Clinical Notes, Suggestions and New Instruments

DEER FLY DESENSITIZATION

J A MEASE MD DUNEDIN FLA

Chrysops is a genus of Tabanid fly. The Florida species is the deer fly or *Chrysops discalis* which may be one of the transmitters of tularemia. This fly is probably familiar to those especially who do any hunting or fishing as in the spring of the year they certainly can bite.

REPORT OF CASE

In 1938 L D, a white man aged 45, came into my office complaining that the deer fly bites he was receiving while working in his grove were getting to a point where they were disabling him. He had never been particularly bothered by them until that spring, although he had been in Florida in the grove business since 1926. However now when he received a bite which was mostly on his wrists as he had begun to protect his face and neck with mosquito netting and his hands with gloves his arm would swell and become painful. The flies, which in previous years had not bothered him, now seemed to be attracted to him and preferred him to any other person working in the grove. They had become so bothersome that it was hard to work in the grove on their account, even though he had protected himself with screening.

His physical examination was negative and he had no history of any allergy. I gave him some ephedrine sulfate and suggested that he use oil of citronella or some other insect repellent. A few days later he came back to the office and his right hand, forearm and arm were swollen to what seemed to me to be twice the normal size. The wrist had areas of erythema, and red streaks radiated upward on the forearm which was very painful. This was about 11 a m and he gave a history of having been bitten by a deer fly the previous morning about 10 o'clock and his hand had begun to swell, continued to swell and became quite painful until the swelling had reached his shoulder by the following morning when he became alarmed and came to the office. His physical examination again was negative except for his right upper extremity. I prescribed a wet magnesium sulfate dressing, epinephrine hypodermically and continuation of the ephedrine sulfate and I advised him to stay indoors. I also asked him to get me some deer flies to make an antigen. He brought me 35 deer flies the next day. His arm was somewhat better but I told him to continue the wet dressings and to return the following day.

I had not had any previous experience in making insect antigens. I macerated 30 of the flies in 30 cc of a buffered solution making a strength of 1 deer fly to 1 cc of the buffered solution and put it through a Seitz filter. The solution was clear and colorless after filtering and was cultured on plain agar and Loeffler's medium and in bouillon for one week. No organisms were found so 0.1 cc of antigen was injected intracutaneously in my arm. There was no reaction, so in twenty-four hours 0.1 cc was injected into the arm of my technician with no reaction. In the meantime the patient's arm had become normal and he was given 0.1 cc intracutaneously of the antigen. The injection caused a red wheal about 1 cm in diameter which had practically disappeared the next day. The second day he was given 0.2 cc subcutaneously. There was no apparent reaction, so two days later he was given 0.5 cc subcutaneously. The arm became red and painful at the site of injection but quieted down within thirty-six hours. Up to this time he had stayed out of the grove now he went back into the grove but protected himself against the deer flies as before. One week after the 0.5 cc dose I gave him 1 cc and continued weekly injections of 1 cc for ten weeks. By this time the deer fly season was past but he had been bitten several times without any swelling.

The following spring 1939 when the deer fly season came he brought me 20 flies and I made another antigen of the same

strength and gave him 0.1 cc intracutaneously, two days later 0.2 cc subcutaneously and two days later 0.5 cc subcutaneously. There was very little reaction, so two days later he was given 1 cc subcutaneously and 1 cc for weekly intervals for three weeks, that is four 1 cc doses. None of these injections appeared to give him any reaction. All during this time he was working in the grove and was bitten a few times by the deer flies, but the reaction was never more than a slight transient wheal. The patient for four years now has worked in the grove during the deer fly season and has had no abnormal swellings from the bite of these flies.

COMMENT

As far as I can find, this is the only case on record in which the bite of the deer fly has caused enough swelling and pain to render a person incapable of work.

The patient became increasingly sensitive to the repeated bites and rapidly desensitized by the injection of the extract made from the whole fly.

After becoming desensitized the patient did not attract the deer flies any more than if as much as the other men working in the grove. Of course this is his statement.

The desensitization has persisted now for four years.

HUMAN TRICHINOSIS FOLLOWING INGESTION OF BEAR MEAT

ROBERT S WESTPHAL MD ALBANY N Y

It is generally considered that 90 per cent or more of human trichinosis occurs as a result of the ingestion of pork. However, according to reports from other areas 'both bears kept in captivity and those in their native habitat show a definite heavy infection with trichinellosis'.¹ Between 1930 and 1935, 29 cases with three deaths were reported by Geiger and Hobmaier as due to the eating of bear meat in California and most of these infections occurred from the ingestion of jerked meat. These authors mentioned also the possibility of the infection of rats, wild hogs, dogs, cats, foxes, coyotes, badgers and ferrets. As a consequence of their findings they suggested careful disposal of carcasses of any of these animals, especially in cities and zoological gardens.¹ Hall² reports 2 or 3 cases of trichinosis resulting from eating beef several cases from bear meat and 1 from dog meat. It is interesting to note that trichinosis in swine is rare in Great Britain, but it is endemic in rats.³ Other authors⁴ present evidence showing that any game or fur bearing animal may be infected.

To my knowledge no case of human trichinosis has been previously reported following the ingestion of bear meat in New York State.

On Dec 17 1942 a report was received in the Albany District Office of the New York State Department of Health suggesting the possibility of a case of trichinosis in a neighboring community. R D, a white man aged 38 stated that on December 5 he had a severe frontal headache which had persisted intermittently until the time of the investigation. There were no other symptoms until December 10 when the patient noted puffiness of the eyelids with some injection of the scleral blood vessels. He sought the advice of an ophthalmologist, who suspecting trichinosis referred him to an internist. The diagnosis was confirmed and the patient advised to remain in bed. He was not hospitalized. On December 14 fever was noted for the first time when it reached a peak of 102.6 F and fluctuated between 99 and 101 F for the next three days. At the time of the visit of the investigator at the home there was no fever present. Also on December 14 the patient began to complain of pain in the muscles of the neck and in the wrists the latter being very transient in nature. Examination of the muscles of the neck revealed no tenderness to pressure.

2. Hall M C. Pub Health Rep 73 1-72 (July) 1938.

3. Beeson P B. Proc Roy Soc Med 34 8 (July) 1941.

4. Committee appointed by Advisory Council on Live Stock and Meat Research. Trichinosis and Some Other Infections with Trichinella Spiralis. J A M A 114 (Jan 6) 1940. Wright W H. Am J Hyg 29 119 (Feb) 1939. Ruhl H. Schweiz Arch Tierb 25 10 1937. Kerr K L. South M J 33 1151 (May) 1940.

No swelling existed, but the patient thought there had been slight swelling over the right trapezius muscle. No gastrointestinal symptoms were noted until December 16, when slight nausea occurred. There was no vomiting or diarrhea, and the nausea lasted less than twenty-four hours. Differential blood count on December 12 revealed a 10 per cent eosinophilia.

The attempt to determine the source of *Trichinella spiralis* was productive of almost too many leads. On November 14 the patient ate bear meat at his own home. This was thought to be slightly rare. Bear meat was consumed on several occasions between that date and November 30, and during this period approximately 12 other persons had eaten of the same portions of the animal. On November 16 the patient had eaten rare roast pork at a dinner served to 22 persons. On November 19, on returning from a hunting trip in a neighboring county, he had stopped at a small tavern where he ate four small slices of smoked sausage along with a glass of beer. Two other men who were with him had eaten large quantities of the sausage, estimated to be about a half a pound per man. On November 30 the patient attended another supper at which meat loaf was served. He thought the loaf contained pork but had been well cooked. A total of 55 persons had eaten of the foods indicated but no one else had become ill.

Of these foods only the bear meat was available for analysis. It had been in cold storage at about 10 F° for forty-five days preceding laboratory examination on January 14. The bear had been shot in northern New York State at a location about 30 miles from the nearest village. Examination of a portion of the muscle from the shank revealed *Trichinella spiralis*.

Special Article

HANDBOOK OF NUTRITION XIII

FOODS OF ANIMAL ORIGIN

H. C. SHERMAN, PH.D.
Professor of Chemistry, Columbia University
NEW YORK

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

NATURAL AND ECONOMIC RELATIONSHIPS

Grouped according to natural relationships and then arranged in descending order of economic prominence, the chief types of food of animal origin are as follows:

1 Meats, including fish and poultry, which together command about one fourth¹ of the average American expenditure for food.

2 Milk in its various forms, including cheese, cream and ice cream, representing usually one tenth to one-eighth of the food budget.

3 Butter and other animal fats, about one tenth.

4 Eggs, about one twentieth.

5 Shellfish, which occupy but a small place in the nation's food budget but lend interest to variations in the dietary.

While this sketch will be systematized largely in terms of this fivefold grouping of its subject matter, it will also be possible to avoid repetition by arranging the discussion according to successive aspects of nutritive value.

Owing to lack of space, this article is abbreviated in THE JOURNAL by omission of table 1. The complete article will appear in the Handbook of Nutrition.

¹ Here and elsewhere such quantitative statements are to be somewhat flexibly construed, because in food statistics the fat meats are sometimes included under meats and sometimes under fats.

PHYSICAL STRUCTURE, PROXIMATE COMPOSITION, PROTEIN AND ENERGY VALUES IN NUTRITION

Meats, Poultry and Fish—In recent years pork has somewhat outranked beef in the American food supply, with lamb and mutton occupying a place far below that of beef and veal. The slaughtering of the meat animals of these three species is a highly centralized industry in the sense that a large proportion of the animals raised for meat are slaughtered in large establishments.

In the case of swine the head is left on the dressed carcass, while with cattle, sheep and lambs the head is removed and the dressed carcass divided longitudinally by splitting the backbone. For this reason and also because of greater fatness the dressed weight of swine is about 80 per cent of the live weight, of beef it is about 60 per cent, of lamb and mutton, about 45 to 50 per cent. Of the butcher's meat about 97 to 98 per cent is muscle, with its accompanying adipose tissue and bone, and only about 2 to 3 per cent is liver. That there is no way of increasing the ratio of liver to muscle meat is of course an obvious fact yet one which often seems to be forgotten when liver is emphasized as a food. Liver can never take a large part in the general food supply, its importance in dietetics lies in getting it consumed by the patients who specifically need it rather than in teaching other people to want it.

The proximate composition and energy value for each sufficiently important food of animal origin is given in table 1, based on the recent government compilation of such data for these and other American food materials.

Market classes and grades of beef and lamb relate to physical properties of the meat which, except as fat affects both, have little if any nutritional significance. Such conventional preferences should be reexamined from time to time in the light of newer knowledge. For example, the fashion has been to prefer that meat fat be firm and white, whereas we now know that a softer, yellower meat-fat is apt to be superior nutritionally.

The muscle tissue, considered separately from all deposited fat, i. e. "clear lean" meat, is of fairly constant composition—about 1 per cent of total mineral matter, 20 to 25 per cent of protein and the rest water. There is somewhat less protein and more water in the muscle tissue of fish than of land animals, and in young than in mature animals of a given species, but among the meats and fish ordinarily entering into the human diet any the latter differences are not of such degree as to have much effect on nutritive values.

The outstanding source of difference in the nutritive character of meats is the widely varying proportion of fat. The fatty layers, or masses or adipose tissues, of meat may be thought of as similar in composition to butter—80 to 90 per cent of actual fat, with about 15 per cent of water, small amounts of protein and salts.

The approximate average percentages of protein and fat have been determined for many kinds and cuts of meat as illustrated in table 1.

This table also shows the proximate composition and energy values of the other chief foods of animal origin.

In composition and energy value there is no distinct gap between the fat meats and the commercial fat.

² Chatfield, Charlotte, and Adams. Georgian. Proximate Composition of American Food Materials. Circular 549. U. S. Dept. Agriculture. June 1940.

Fat pork is, in fact, sometimes grouped with meats and sometimes with fats. If this is kept in mind it will clear up some apparent discrepancies in food statistics.

Eggs, like lean meats, are about three fourths water, with about 1 per cent of mineral matter, but the organic matter for the egg as a whole consists about equally

TABLE 2—Approximate Average Relationships of Mineral Elements to Protein in the Chief Types of Food of Animal Origin

	Grams of the Mineral Element per Hundred Grams of Protein			
	Meats	Fish	Eggs	Milk
Calcium	0.038	0.109	0.453	3.572
Magnesium	0.116	0.153	0.101	0.343
Potassium	1.624	1.671	1.078	4.056
Sodium	0.471	0.373	1.094	1.457
Phosphorus	1.078	1.148	1.750	2.657
Chlorine	0.378	0.598	0.938	3.028
Sulfur	1.146	1.119	1.530	0.971
Iron	0.015	0.0055	0.074	0.0057

of protein and fat. Egg white is about seven eighths water and one eighth protein, while egg yolk is about one half water, one third fat and one sixth protein.

The actual averages of these constituents for all the foods here mentioned as well as other foods of animal origin, as officially published by the U. S. Department of Agriculture, are given in table 1.

Milk, Cream and Cheese—While none of the staple meats contain any significant amount of carbohydrate, milk contains more of lactose than of either protein or fat. Milk is also much more watery than even the leanest meat, the latter having about one fourth solids while fresh whole milk has only about one eighth, and fat free milk (the analogue of clear lean meat) is more than nine tenths water and less than one tenth solids.

Cream differs from milk simply in containing more of the fat globules with a consequent (relatively small) diminution of the watery part (aqueous phase) of the milk in which its carbohydrate (lactose, milk sugar) is dissolved and in which its proteins and mineral matters are partly dissolved and partly held in aqueous dispersion. The fat globules constitute one part in 25 or 30 of average whole milk. Hence cream containing, say, five or six times as much fat as milk does, will still contain four fifths to five sixths as much as milk does of all the other milk constituents. Enrichment of the dietary in these milk constituents is often nutritionally desirable. It is therefore important to remember that if milk itself is not relished, cream may be used instead.

Cheese is another form of milk which may be more interesting to the consumer than the milk itself. In general, an ounce of cheese is equivalent to a pint of milk, though of course most of the lactose, certain fractions of the protein, mineral and vitamin values have escaped in the whey. The cheese retains, however, nearly all of the fat and fat soluble vitamins of the milk and much the greater part of the protein, the calcium and the riboflavin. (All this, of course, refers to real cheese, not cottage cheese, which retains very much less of the mineral and vitamin values.)

Shellfish share with milk the property of containing a significant percentage of carbohydrate (in their case glycogen), but otherwise their composition resembles that of meats, fish and poultry.

MINERAL ELEMENTS AND THEIR NUTRITIONAL AVAILABILITY

Statements regarding the nutritional characteristics and nutritive values of meats are complicated (and may become confused or misleading) by the wide differences in fatness and resulting chemical composition among meats. This is true not only as between different species used as human food but also as between different individuals of the same species (and even of the same sex and age) and often as between different cuts from the same carcass.

Considered aside from the glandular organs and from bone, meats may be regarded as essentially composed of muscle tissue and adipose tissue, but these in quite variable proportions (quantitative relations).

Relatively few samples of meat have been analyzed for individual mineral elements. These have been chiefly clear lean specimens because it has been considered and is doubtless true that the mineral elements, like the proteins, belong essentially to the protoplasmic part of the meat. From the same point of view it may be expected that, as far as the influence of the varying amounts of fat on the mineral values of the meat are concerned, the amounts of the mineral elements will run essentially parallel with the amounts of protein. Hence in calculating the nutritive values of dietaries or larger food supplies one may, after computing the total meat protein from such data as those in table 1, then estimate the mineral contents by relation to the protein, using conventional average figures such as those given for meats and fish separately in table 2. For comparison table 2³ shows the amounts of the chief mineral elements for milk and for eggs as well as for meats and for fish, each per hundred grams of protein in the respective food.

TABLE 3—Composition of Meat Samples (Forbes and Swift)

Sam- ple No.	Kind of Meat	Iron per Cent	Nitro- gen per Cent	Protein (N x 6.25) per Cent	Ether Ex- tract per Cent	Mois- ture per Cent	Mg Iron per 100 gms of Pro- tein
105	Bacon, cured	0.0013	1.67	10.44	64.10	22.31	12.5
107	Ham, cured	0.0014	3.37	21.06	13.60	64.61	6.6

108	Pork hind quarter	0.0015	3.14	19.63	10.54	69.07	7.6
112	Lamb shoulder	0.0016	3.01	18.81	6.94	72.95	8.5
113	Lamb hind quarter	0.0016	3.25	20.31	5.27	75.59	7.9
109	Beef rib	0.0024	3.24	20.25	6.05	72.70	11.9
100	Beef round	0.0025	3.55	22.19	3.48	74.65	11.3
101	Beef loin	0.0025	3.29	20.56	6.59	72.02	11.2
103	Beef chuck	0.0025	3.17	19.81	7.13	72.84	10.6
109	Veal fore quarter	0.0023	3.47	21.69	1.70	76.08	10.6
110	Veal hind quarter	0.0027	3.54	22.13	1.54	76.68	11.2
116	Veal kidney	0.0040	2.61	16.31	4.17	77.82	24.5
111	Beef heart	0.0044	2.59	16.19	4.94	78.91	21.2
117	Beef brain	0.0053	1.68	10.50	7.89	79.15	50.6
104	Beef liver	0.0082	3.30	20.63	4.63	68.33	29.7
115	Beef spleen	0.0138	3.03	18.94	1.90	77.50	71.9
106	Beef kidney	0.0188	2.58	16.13	1.65	78.67	116.6
118	Beef blood	0.0444	2.87	17.94		89.99	24.5

Especially in the case of the iron contents of meats it was never intended to imply that the approximate average relationship indicated in table 2 should hold good for each different organ and tissue. Forbes and Swift⁴ have published the results of their determina-

³ By permission of the Macmillan Company publishers the data here given are in part taken from pages 563 and 564 of Sherman's *Chemistry of Food and Nutrition*, ed. 6, May 1941 and in part adapted from the extensive table of which these pages are a part.

⁴ Forbes, L. B. and Swift, R. W. *Iron Content of Meat*. J. Biol. Chem. 67: 517 (Feb.) 1926.

tions of iron in 18 individual samples of meat (and a sample of blood). These results are here reprinted, by permission, as table 3.

When account is taken of the relative quantities in which the different kinds of meat enter into the American food supply, the data for iron in tables 2 and 3 are seen to be quite consistent.

Less consistent are the published findings as to the nutritional availability of the iron of meats. Even the papers of such eminent investigators as Whipple and Elvehjem give such divergent impressions that it seems still an open question whether the different methods commonly accepted as indicative of the relative quantitative utilization of food iron in nutrition should be considered as measuring availability in the same (or in any closely comparable) sense. Numerical expressions of availability or utilization of meat iron in nutrition are therefore omitted here lest they should confuse instead of clarifying the subject.

TABLE 4—Approximate Percent Vitamin Values of Some Typical Foods of Animal Origin

Food	Data to May 1, 1943		
	Vitamin A Value, International Units per 100 Gm.	Thiamine Micrograms per 100 Gm.	Riboflavin, Micrograms per 100 Gm.
Pork lean	Negligible	990	210
Bacon medium fat raw	Negligible	100	100
Beef clear lean raw	Negligible	160	20
Lamb, lean raw	Negligible	200	20
Chicken dark meat	Negligible	200	20
Chicken light meat	Negligible	200	60
Eggs	100	100	30
Egg white	Trace	Trace	20
Egg yolk	4000	400	50
Milk	100	60	20
Cream (21% fat)	1500	40	160
Ice cream (1% fat)	800	50	200
Cheese (7% fat)	2000	40	40
Butter	1500	Negligible	Negligible
Oysters	200	200	Undetermined
Milk dried skim	Undetermined	500	2000

We know of no reason for doubting the nutritional availability of the other mineral elements of meats and of all the mineral elements of milk and eggs.

VITAMIN VALUES

The vitamin A value of a dietary, and of most of the individual foods of animal origin, is due (1) to vitamin A itself and (2) to its precursors, which are formed in plants and to some extent are stored in the animal body, where, however, the greater part is changed into vitamin A. Corresponding with the nutritional importance of vitamin A we find that evolution has accentuated the property of transfer of this vitamin from one generation to the next through milk and eggs. Most of the vitamin A which the body itself retains is held in the liver, whose content of this and other vitamins thus varies so greatly with the individual nutritional background as to make it seem nearly meaningless and perhaps misleading to attempt numerical averages in table 4. Taking account of available quantities, milk (including cheese, cream and ice cream), butter, margarines enriched with vitamin A from fish liver oils, the fish oils themselves and eggs are the chief sources of animal origin.

Of the B vitamin group our knowledge is as yet very uneven. Approximate average thiamine and riboflavin contents of typical foods of animal origin, based

on a study of all the data available to June 1942 (including unpublished findings consulted through the courtesy of Dr. C. N. Frey, Dr. R. R. Williams and Dr. V. H. Cheldelin, as well as my co-workers at Columbia) are given in table 4. Lean meats, eggs, milk, cheese, cream and ice cream are all noteworthy sources of riboflavin when taken in the quantities which are normal to typical American dietaries. In such dietaries, milk and its products will furnish something like one half of the total riboflavin, and meat and eggs the greater part of the remainder. Of thiamine the foods of animal origin are not such prominent contributors, a relatively larger share of the responsibility for the thiamine intake resting on enriched and whole grain breadstuffs and cereals. Lean pork is richer in thiamine than other common meats.

Niacin (nicotinic acid) is qualitatively well established as an antipellagic factor, but the estimates of quantities of niacin contained in foods or concerned in nutrition are as yet very tentative and uncertain, and it is a mistake (though doubtless one for which we scientists are ourselves responsible) to suppose that niacin bears any such clearcut relation to pellagra as, e.g., ascorbic acid bears to scurvy. On paper, pellagra may have been redefined as nicotinic acid deficiency, but the typical pellagrin actually needs so much more than this one factor that his case is probably not so parallel with that of the blacktongue dog as has often been assumed, and for the same reasons as well as because of the uncertainties of present analytic methods, figures comparing the estimated nicotinic acid contents of foods are apt to give very misleading impressions. Therefore I do not attempt to include them in table 4, or the other B vitamins now recognized but of which our knowledge is as yet little more than qualitative.

From a combined study of the earlier work of Osborne and Mendel and the recent work of Elvehjem and his co-workers at Wisconsin, it appears probable that both milk and meat contain all the B vitamins concerned in mammalian nutrition.

Ascorbic acid has been shown by Bessey and King⁵ to occur normally in amounts demonstrable by modern methods in animal tissues generally, especially the glandular organs. Muscle, however, contains very little, and this is further reduced by the time the meat is served at table. For the purposes of practical dietetics, therefore, the vitamin C value of meats is considered negligible, also that of eggs. Fresh milk and oysters furnish about 2 to 3 mg. of this vitamin per hundred grams. The extent of the loss in present day pasteurization of milk has been repeatedly found to be about one fifth. In practice we look to fruits and vegetables rather than to the foods of animal origin for our dietary vitamin C.

Vitamin D is present in only negligible amounts in meats generally, slightly more in liver, milk and butter, distinctly more in eggs. The amounts contained in these foods have, however, been but little studied, since it has been shown that the fish liver oils contain very much greater concentrations and also that milk can readily be fortified to make the now familiar "vitamin D milk" of commerce.

⁵ Bessey, O. A. and King, C. G. The Distribution of Vitamin C in Plant and Animal Tissues and Its Determination. *J. Biol. Chem.* 103: 687-698 (Dec.) 1933.

For the reasons just given the data on vitamins C and D naturally present in foods of animal origin are omitted from table 4

Losses of Vitamins in Cooking—Losses in cooking are usually larger for vitamin C than for any of the other vitamins. Several independent investigations have consistently shown the diminution of 18 to 20 per cent in the vitamin C value of milk in modern pasteurization and there is no reason to suppose that the loss would be very different in ordinary cooking operations. There has been no occasion for the comparison of different foods of animal origin in this respect, as so few of them have measurable vitamin C value. Cooking losses of thiamine and riboflavin seem to be higher for meat than for milk, with eggs probably occupying an intermediate position but yielding extremely variable results according to the mode and conditions of cooking. The cooking losses of thiamine and riboflavin in meats have also seemed to vary greatly in the investigations thus far reported, and much additional experimental work in this field is now proposed and in some cases in progress. Hence it seems better not to record in numerical form any findings which could now be given since we may hope that more conclusive data will be available soon.

OTHER DIETARY CONSIDERATIONS

There is experimental evidence, the fuller explanation of which is still under active research, that some fats of animal origin have special values in nutrition beyond those due to the hitherto well established factors. To Dr Burr in Minnesota and to Dr Hart in Wisconsin, who with their respective co-workers are outstandingly engaged in two such lines of research, I am indebted for personal communications bringing their findings up to May 1942 as follows. Dr Burr holds that, while the explanation is still a research problem, a few fats including lard are superior to many other food fats as shown by growth experiments with young rats, and Dr Hart writes "Our work with the 21 day old rat supports the conclusion that there are in butter fat saturated fatty acids of high molecular weight which accelerate the rate of growth as compared with such vegetable oils as corn oil, cottonseed oil, soybean oil, coconut oil and olive oil."

While meat, eggs and milk are much alike in the nutritional efficiency of their proteins, yet these are accompanied by other nutrients which in some respects are quite different either in kind or relative amount, with the result that meat and eggs do not assist the body, as does milk, in the maintenance of its alkali reserve and of a favorable intestinal flora, and hygiene of the alimentary tract. Also the larger the proportion in which milk is used as source of animal protein the better insured is the liberality of calcium intake which is now known to be more important at all ages than hitherto understood.

Limitation of space forbids discussion here of the relative economy of the different foods of animal origin from the point of view of the percentage of the food-money which is spent for each and its percentage contribution to each of the nutrient factors of the dietary, but this is something which physicians in the future may well carry in mind now that we know how greatly health depends on the wise investment of the money available for food.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

PROCAINE HYDROCHLORIDE (See New and Non-official Remedies, 1942, p. 56)

The following dosage forms have been accepted

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Ampuls Solution Procaine Hydrochloride 2% W/V 2 cc Each cubic centimeter contains 0.02 Gm of procaine hydrochloride, 0.005 Gm of chlorobutanol and 0.001 Gm of sodium bisulfite in distilled water

Ampuls Solution Procaine Hydrochloride 2% with Epinephrine 1:20,000 3 cc Each cubic centimeter contains 0.02 Gm of procaine hydrochloride, 0.05 of epinephrine, 0.005 Gm of chlorobutanol and 0.001 Gm of sodium bisulfite in distilled water

Solution Procaine Hydrochloride 2% W/V 30 cc and 100 cc vials Each cubic centimeter contains 0.02 Gm procaine hydrochloride, 0.005 Gm of chlorobutanol and 0.001 Gm of sodium bisulfite in distilled water

Solution Procaine Hydrochloride 2% with Epinephrine 1:25,000 30 cc and 100 cc vials Each cubic centimeter contains 0.02 Gm of procaine hydrochloride, 0.04 mg of epinephrine, 0.005 Gm of chlorobutanol and 0.001 Gm of sodium bisulfite in distilled water

THIAMINE HYDROCHLORIDE (See New and Non-official Remedies 1942 p. 555)

The following dosage forms have been accepted

DRUG PRODUCTS CO., INC., LONG ISLAND CITY, N. Y.

Hyposols Solution of Thiamine Hydrochloride Crystals, 100 mg per cc 10 cc and 30 cc vials Preserved with 0.5 per cent of chlorobutanol

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Solution Thiamine Hydrochloride, 100 mg per cc 5 cc, 10 cc and 25 cc vials Preserved with 1 per cent benzyl alcohol

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Solution Thiamine Hydrochloride, 100 mg per cc 10 cc vials Preserved with 0.5 per cent chlorobutanol

JOHN WILEY & BROTHER, INC., PHILADELPHIA

Ampoule Solution Thiamine Hydrochloride, 100 mg per cc 10 cc Preserved with 0.5 per cent chlorobutanol

DIODRAST (See New and Nonofficial Remedies, 1942, p. 309)

The following dosage form has been accepted

WINTHROP CHEMICAL CO., INC., NEW YORK

Ampules Diodrast Sterile Solution (35 Per Cent, Weight/Volume) 30 cc

MENADIONE (See New and Nonofficial Remedies, 1942, p. 584)

The following dosage form has been accepted

E. R. SQUIBB & SONS, NEW YORK

Solution Thyloquinone (in Corn Oil) (Oral), 1 mg per cc 5 cc, 10 cc and 50 cc vials Each cubic centimeter contains 1 mg of thyloquinone

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies 1942 p. 513)

The following dosage form has been accepted

PITMAN-MOORE COMPANY, INDIANAPOLIS

Diphtheria Toxoid (Alum Precipitated, Refined) Two 1 cc vials (2 doses), 5 cc vials (5 doses) and 10 cc vials (10 doses) Preserved with 1:10,000 merthiolate

RABIES VACCINE (SEMPLÉ) (See New and Non-official Remedies 1942 p. 506)

The following dosage form has been accepted

PITMAN-MOORE COMPANY, INDIANAPOLIS

Rabies Vaccine (Killed Virus) Semplé Method 1 cc vials packaged in units of seven vials Preserved with 1 per cent of phenol

SATURDAY, MAY 22 1943

INDUSTRIAL SOLVENTS

Most important in the field of industrial toxicology is the rapid development of new solvents for use in a variety of manufacturing processes. Many of these solvents were chemical curiosities a few years ago, now they are sold in canboy or even tank car lots. Inevitably the medical profession is consulted as to the possible harmful effects of using solvents and especially from breathing them.

Possible dangers from the use of these new chemicals are appreciated by the chemical industry. Manufacturers often establish research fellowships or special contractual arrangements with universities such as Pennsylvania, Harvard and Cincinnati, with specially qualified institutions such as the Saranac Laboratories and the Industrial Hygiene Foundation and with private consultants. Some manufacturers have well equipped laboratories of their own and staffs of specialists whose sole work concerns the industrial toxicology of their own products. The industrial hygiene laboratories of the Public Health Services at Bethesda, Md., are publishing an ever increasing volume of fundamental researches on industrial toxicology which are of the utmost importance to industry.

With this new information it is surprising that there has not been more interest in one of the fundamental problems of industrial toxicology—how much of some particular solvent is absorbed by a man exposed under definite conditions and how rapidly he excretes it when exposure ceases. In a series of papers which have proved of great practical value in anesthesia, Haggard of Yale showed by animal experimentation how two types of solvents, ethyl alcohol and common ether, are absorbed, metabolized and excreted. Of special significance was his proof of the fundamental physicochemical nature of the general processes involved. Necessarily he used doses measured in percentage or parts per hundred. He showed that ether was absorbed and excreted almost wholly by way of the lungs, while alcohol, which is highly soluble in body fluids, is

excreted both in urine and in exhaled air and also is metabolized.

In the paper by McKee and others,¹ analogous studies with carbon disulfide are described. The important difference between McKee's and Haggard's work lies in the difference in the compounds studied, but more particularly on the concentration levels or doses used. McKee could use small amounts (parts per million) and thus approximate industrial conditions. Carbon disulfide happens to be determinable chemically in minute quantities, a fact which made the work possible.

Carbon disulfide is absorbed largely by inhalation, the time required to produce saturation of the blood depends entirely on the concentration in the air breathed and is proportionally longer for higher air concentrations. The major part of the absorption of carbon disulfide at the low concentrations such as one encounters in industry takes place in the first thirty minutes, although complete saturation of all body tissues probably takes somewhat longer. Elimination by exhalation follows the same principles, but a considerable portion of the vapor is metabolized, which probably accounts for its recognized toxicity. The amount of muscular effort being expended by the workman exposed, the temperature of the air breathed and the relative humidity have no really significant effect on the amounts absorbed—their effect is wholly physicochemical.

Whether a new solvent is largely metabolized like alcohol or is excreted by breath like ethyl ether (carbon disulfide falls somewhere between the two) should be determined and the rate of absorption and excretion defined. Such figures enable industry to set safe concentration limits in the air of workrooms, a point of the greatest importance in industrial medicine.

GROWTH ACCELERATING PROTEIN

Isolation of a pancreatic protein that has remarkable growth promoting properties has been reported recently by White and Sayers² of Yale University. The protein was originally obtained by Kazel³ as an insoluble residue after acid-alcohol extraction of the finely minced frozen beef pancreas. It was rendered lipid free by subsequent continuous extraction with acetone. Partial analysis of the oven dried (105 C) end product showed that it contained an average of 16.2 per cent of nitrogen, 1.56 per cent of phosphorus, 1.56 per cent of tryptophan and 3.85 per cent of tyrosine, with an atomic purine nitrogen-phosphorus ratio similar to that calculated from Loring's data³ for certain nucleic acids. Purine determinations suggested a nucleic acid content of 10 to 14 per cent.

1 McKee, R. W., Kiper, C. M., Fountain, J. H., Riskin, A. M. and Drinker, P. A. Solvent Vapor Carbon Disulfide Absorption Elimination, Metabolism and Mode of Action this issue p. 217.

2 White, Abraham and Sayers, M. A. Proc. Soc. Exper. Biol. & Med. 51: 270 (Nov.) 1942.

3 Kazel, L. A., Westfall, R. J., Cieresko, I. S., Risley, E. A. and Arnov, L. E. Proc. Soc. Exper. Biol. & Med. 51: 268 (Nov.) 1942.

3 Loring, H. S. J. Biol. Chem. 130: 251 (Sept.) 1939.

Recently weaned male white rats were placed on a basal diet containing 22 per cent of this protein or the nitrogenous equivalents of other proteins. The control proteins included commercial casein, dried whole beef serum, heat coagulated beef serum protein, pumpkin seed globulin and soy bean protein. Each diet contained 25 per cent of crisco, 35 per cent of starch and 4 per cent of Osborne-Mendel salt mixture with a daily supplement of 400 mg of dried yeast and 200 mg of cod liver oil.

An extraordinary difference was observed in the average daily consumption of these diets, the lowest ad libitum consumption (47 Gm) being with the diet containing 25 per cent of heat coagulated beef serum protein. The daily consumption of the diet containing 22 per cent of pancreas was more than twice that amount (108 Gm), other diets occupying intermediary positions. The Yale physiologists offer no reason to account for this remarkable difference in daily food intake.

Even greater differences were noted in the nutritional value of the different diets. Here the slowest growth rate was recorded with animals fed 21 per cent of soy bean protein each daily ingested gram of this diet leading to a daily increase of only 0.19 Gm in body weight. The diet containing 22 per cent of pancreatic protein was three times more effective, giving a 0.55 Gm daily increase in body weight per gram of food intake. With the exception of casein, other proteins occupied intermediary positions. Commercial casein also gave a daily increase in body weight of 0.55 Gm per gram of ingested basal diet. Here also no theory was suggested to account for the remarkable nutritional differences.

As a result of the increased daily consumption of the diet containing pancreatic protein and its exceptionally high nutritional value, an extremely accelerated growth rate was recorded for the pancreas fed rats. During the first twenty-eight days the control soy bean diet led to only a 28 Gm increase in body weight. The pancreatic protein gave a twenty-eight day weight increase six times as great, i.e. 166 Gm. The second best protein (casein) led to a weight increase of 133 Gm during the same length of time, other control proteins occupying intermediary positions. Comparison between the two superior proteins (pancreatic residue and casein) was continued for a hundred and forty-five days, at the end of which time one of the rats that had been fed on pancreas had reached a body weight of 640 Gm, while its casein control litter mate weighed only 490 Gm.

The physiologists emphasize the fact that the ratio of body length to body weight remained constant throughout all their experiments.

With the present overemphasis on the health producing and growth promoting properties of vitamins,

proof of equally definite acceleration of growth by the use of certain selected proteins is of basic clinical interest. The nutritional inferiority of soy bean protein is particularly suggestive, even though "soy bean dwarfism" has thus far been demonstrated only with white rats.

RESULTS OF HOSPITAL TREATMENT OF NARCOTIC DRUG ADDICTS

A thorough, well organized follow-up study¹ has been made of 4,766 male patients discharged from the United States Public Health Service Hospital at Lexington, Ky., during the period from Jan. 1, 1936 to Dec. 31, 1940. All these patients had received treatment in the hospital for addiction to narcotic drugs. The only narcotics mentioned in the report are opium and its derivatives. The follow-up was carried out between July 1 and Dec. 31, 1941. In other words, at least six months after the discharge of the last patient in 1940.

The results of the follow-up are presented in detailed tabulations, which are analyzed and discussed from various points of view. The patients fall into four general classes: voluntary, probationer patients, paroled prisoners and prisoner patients. A probationer patient is a narcotic drug addict who for violation of a federal law, has been given a probationary sentence on the condition that 'he goes to one of the United States Public Health Service hospitals either at Lexington or Fort Worth for treatment and remains until pronounced cured by the medical staff.'

The state as to addiction of 39.6 per cent of the 4,766 discharged patients could not be determined, 7 per cent had died after leaving the hospital, 39.9 per cent had relapsed to the use of drugs and 13.5 per cent were still abstinent. Excluding the dead and the unknown, 74.7 per cent had relapsed and 25.3 per cent had remained abstinent.

The analysis of the facts about the different classes of patients led to the important conclusion that the most successful program of treatment for narcotic drug addicts includes a comparatively short period of hospitalization, not less than two months but not more than five, with acceptable employment as a prerequisite for release, and then adequate extramural supervision for three years with periodic check-up examinations. This means that for patients placed on probation for three to five years the one innovation necessary to carry this program into effect would be compulsory employment. Periodic check-up services have been initiated at the Lexington hospital. The general belief that a drug addict can never be cured is not supported by this follow-up study.

Current Comment

EPIDEMIOLOGY OF RHEUMATIC FEVER

During the past ten years great activity has taken place in research on rheumatic fever. As pointed out by Paul,¹ appreciable strides have been made in understanding the epidemiology of rheumatic fever, owing in large part to the notable contributions of Hedley on rheumatic heart disease in Philadelphia hospitals. The appreciation of the pathogenesis of this disease has taken a new turn with the recognition of its close relationship to hemolytic streptococcus infections—a development based largely on the work of Coburn. Observations along these lines have wrought a profound change in present conceptions regarding the nature of rheumatic fever. The recent publication of a new edition of a book on the epidemiology of rheumatic fever, the first edition of which was published in 1931, constitutes a welcome summary at this time. It reviews the present status of the associations between rheumatic fever and acute hemolytic streptococcus infections, the geographic prevalence and climatic influences on the disease, the age, sex and racial prevalence, living conditions, the rheumatic family and like items of epidemiologic significance. There are four appendices. The professional work of the author, Dr. Paul, and of the other members of the committee of the American Heart Association interested in the publication of this book assure its authoritative nature.

CITRATE SOLUTION FOR DISSOLVING PHOSPHATIC URINARY CALCULI

The desirability of a method for dissolving urinary calculi in situ by retrograde introduction of a suitably nonirritating solution has long been recognized. Suby and Albright,¹ who have studied this problem for several years, now report their results in 6 selected cases in which phosphatic urinary calculi were treated by the retrograde introduction of a citrate solution rendered less irritable than previously tried solutions by the addition of magnesium. The main object of the treatment was to keep the solution in contact with the stone as much as possible. The actual apparatus employed in each case depended on whether a simple nephrostomy tube, a two way nephrostomy tube, two nephrostomy tubes, a ureteral catheter and a nephrostomy tube, or one or more ureteral catheters were used. Technical aspects also varied, depending on the degree of patency of the ureter and on the amount of irritability of the bladder and urethra. In 2 cases the solution was introduced through ureteral catheters and in the remaining 4 through nephrostomy tubes. In these 6 cases the solution was used successfully for the partial or complete dissolution of stones. One case

is also reported in which the attempted dissolution of a large stone was without success because the solution was prevented from coming in contact with the stone by a thin coating of an unidentified material, possibly an old blood clot. Suby and Albright emphasize that it is necessary to know before attempting to dissolve a stone with this solution, which they call solution G, that one is dealing with a phosphatic stone. Such a stone is composed of calcium phosphate with or without calcium carbonate or magnesium ammonium phosphate or both. Given the necessary indications, this solution appears to provide a practical method for dissolving certain types of urinary calculi.

HEALTH LEAGUE OF CANADA

A report just issued by the Health League of Canada¹ summarizes the work of the league and its several branches. The Health League of Canada has some of the aspects of the American Public Health Association, which, as the professional organization of public health workers, includes Canadian and other North American representatives. The Health League of Canada also has some of the characteristics of the several voluntary health associations in the United States which specialize in the fields of tuberculosis, eyesight conservation, mental hygiene and similar specialties. In its membership the Health League of Canada includes both professional and lay members. There are branches of the league in Quebec Province and Quebec City, Vancouver, Ottawa, Toronto, London and Niagara Falls. It has standing committees of the usual organizational type plus committees on milk, social hygiene, nutrition, industrial problems, diphtheria and publicity. Through this comprehensive official and citizens group the league conducts general educational activities in the health field through the press, the radio and a magazine entitled *Health*. It gives attention to venereal disease control and diphtheria prevention. It advocates universal pasteurization of milk. It has prepared literature and other educational activities in the field of nutrition and industrial health. Public health meetings are organized. The league is financed by endowment, popular grants and donations, tag days and subscription and advertising revenue from its magazine. Its total revenue for twelve months ended April 30, 1942 was approximately \$100,000. The Health League of Canada does through one comprehensive organization approximately the same type of health promotion work for the Dominion as is carried out in the United States by numerous health organizations of mixed professional and lay composition operating in much the same manner. Whereas in Canada coordination is attained through one organization, in the United States it has been attempted through the National Health Council and more recently through the National Conference for Cooperation in Health Education, in which more than forty health agencies are now participating experimentally to determine how efficient cooperation and coordination can be achieved.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PENICILLIN

Statement Released by the Committee on Medical Research

A N RICHARDS, Chairman

This statement is designed to acquaint the medical profession with the progress of efforts which are being made by the Committee on Medical Research of the Office of Scientific Research and Development, by the Division of Medical Sciences of the National Research Council and by certain commercial companies to promote investigation of the therapeutic usefulness of penicillin and to increase the available supply of this remarkable substance. They were initiated and are continuing as a phase of the war effort, directed primarily toward the benefit of our armed forces.

Penicillin was discovered by Fleming in London in 1929. The first information concerning its unique therapeutic possibilities was revealed in the publications in the *Lancet* (1940 and 1941) of experimental and clinical studies by Florey, Chain and their collaborators of Oxford. The intense interest in it now manifest in this country was initiated not only by those papers but by personal communications with Professor Florey during his visit to this country in the summer of 1941.

Florey's visit was arranged by the Rockefeller Foundation. After conferences with interested members of the National Research Council and the U. S. Department of Agriculture, Florey and his colleague Heatley proceeded to the Northern Regional Laboratory of the Department of Agriculture at Peoria, Ill. where studies were at once initiated by Dr. R. D. Coghill and Dr. A. J. Moyer on cultural characteristics of *Penicillium notatum*, the organism which makes penicillin, and on methods of purification of that substance. These studies are still continuing and have been of great value to those who are undertaking the production of penicillin.

Returning from Peoria, Florey consulted with several commercial companies in the hope that they might undertake production developments. His efforts in this direction were supported by encouragement from the Committee on Medical Research and the National Research Council and in the early autumn of 1941 research looking toward production was begun in the laboratories of Merck and Company, E. R. Squibb and Sons, Charles A. Pfizer and Company, the Lederle Company, and perhaps others of which we were not aware. That research has continued, the interest of other companies has been aroused until today some sixteen companies are engaged in or intend to become engaged in the production of penicillin. In no instance has production advanced beyond the pilot plant stage, in the majority it is still in the laboratory stage.

The difficulties which confront large scale production are very great. They arise chiefly from the fact that in the metabolism of the mold only very minute amounts

of penicillin are formed and those only after days of growth. A yield of as much as 1 gram of the purified product from 20 liters of culture fluid would be regarded as exceptionally high. In impure solutions penicillin is unstable, it is destroyed by bacterial or other contaminations to which the culture fluids are highly susceptible. Difficulties have been encountered in choosing the most productive strains of the mold and the most suitable culture mediums in the development of methods for extraction and purification and in stabilization of the purified product.

The first clinical tests of penicillin in this country were reported by Dawson of Columbia in 1941. Other supplies became available in 1942, and in June of that year the Committee on Chemotherapeutic and Other Agents of the National Research Council, under the chairmanship of Dr. Chester S. Keefer, was invited to organize and supervise clinical investigations in selected hospitals, the records to be coordinated by Dr. Keefer and his committee. The costs of these studies, now proceeding in some twenty civilian institutions, are provided by contract with the Office of Scientific Research and Development recommended by the Committee of Medical Research. The results will be published in due course.

Six weeks ago arrangements were made by the Surgeon General of the Army for clinical tests at the Bushnell General Hospital, Brigham City, Utah. There were to be found among soldiers returned from the Pacific area many cases of unhealed compound fractures, osteomyelitis and wounds with long established infections. The results have been so encouraging that plans are now in process for undertaking similar wound studies in ten general army hospitals and venereal disease studies in six. A similar though less extensive plan will be pursued by the Navy.

The results of these investigations thus far have completely upheld the early promise contained in the reports of Florey, Chain and their collaborators. More than 300 patients have been or are being treated with penicillin. There is good reason for the belief that it is far superior to any of the sulfonamides in the treatment of *Staphylococcus aureus* infections with and without bacteremia including acute and chronic osteomyelitis, cellulitis, carbuncles of the hip and face, pneumonia and empyema, infected wounds and burns. It is also extremely effective in the treatment of hemolytic streptococcus, pneumococcus and gonococcus infections which are resistant to sulfonamides. It has not been found effective in the treatment of subacute bacterial endocarditis. Studies of the results of its local application are still inadequate.

Properly made preparations have given no toxic reactions, even from the largest dosage. Its rapid excretion in the urine necessitates frequent administration when given intravenously or intramuscularly.

The work of the coming three months can be expected to result in clearer definition of the conditions in military medicine in which penicillin will be most useful, of its limitations and of the most advantageous as well as the most economical methods of its administration.

At the same time intense efforts are being made by manufacturers to expand production to a point at which it may be made available in significant quantities not only for casualties returned to this country but also for our forces overseas.

Unless an expansion of production takes place at a greater rate than can now be foreseen, the supply for civilian medical needs in the near future will be exceedingly limited.

ARMY

AMERICAN SOLDIERS ESCAPE TYPHUS

Although more than 100,000 cases of typhus fever occurred in North Africa in 1942, American military forces in that region have come through almost untouched by this disease, according to statisticians of the Metropolitan Life Insurance Company. In Tunisia in 1942 there were more than 16,000 cases in Germans more than 35,000 cases in French Morocco 26,000 cases and in Egypt about 23,000 cases. It is likely that the favorable situation will continue with regard to our military forces in that region because our military physicians are alert to the dangers from this disease which is still a menace to the health of the civilian population.

A potentially dangerous situation exists in the battle areas and occupied regions of eastern Europe but the facts are carefully concealed by German censorship. Even in Germany itself, which for generations has been free from typhus, numerous cases have been reported the first seven weeks of 1943 showing 800 or nearly twice the number of cases for the first quarter of 1942. There were more cases in Rumania in 1942 than at any time since 1911 for February 1943 the cases were said to have been 30 per cent greater than in the preceding February. Typhus is more prevalent in Bulgaria and in Hungary this spring than in 1942, some outbreaks have occurred even in France. The starved and ragged populations of eastern Europe are fertile soil for the spread of typhus. Until the axis armies are driven out of these countries and order and public health administration restored and the people get enough food and clothing, typhus will not be brought under control as it is among our own troops.

ANTITYPHUS DUSTING POWDER

Millions of 2 ounce cans of body dusting powder for the U. S. Army, already in the packs of North African troops, will protect overseas personnel against typhus-carrying pests, it has been announced by the Grasselli Chemicals Department of the du Pont Company. Though the powder contains some pyrethrum, an increasingly scarce standard ingredient of insecticides, according to a company official, substantial quantities are being saved by use of a du Pont developed synthetic. Laboratory tests have shown that the replacement compound, called IN-930, increases the efficiency of the pyrethrum in the powder.

FIRST WOMAN PHYSICIAN COMMISSIONED UNDER NEW LAW

Major Margaret D. Craighill, former dean of the Woman's Medical College in Philadelphia, who is the first woman physician to be commissioned directly in the Army under recently enacted legislation (*THE JOURNAL*, May 8, p. 123), will soon report for duty in the preventive medicine section of the Surgeon General's Office, Washington, D. C. According to the *New York Times*, Dr. Craighill's father and grandfather, Col. William E. Craighill and Gen. William P. Craighill respectively, were West Point graduates. Dr. Craighill was born in Southport, N. C., and grew up in Mobile, Ala., and in Portland, Maine. She received an A. B. degree from Wisconsin University in 1920 and an M. S. in 1921, and an M. D. degree from Johns Hopkins University in 1924. The next year she

interned there in gynecology and surgery. She was assistant in pathology at Yale University Medical School from 1925 to 1926 and assistant resident in gynecology at Johns Hopkins from 1926 to 1928. Dr. Craighill is a specialist certified by the American Board of Obstetrics and Gynecology.

PROCESSING PHYSICIANS, DENTISTS AND VETERINARIANS IN THE FIELD

1 This memorandum from the Officer Procurement Service, Washington, D. C., May 13, supplements the basic instructions on the subject contained in FT-34, Feb. 27, 1943. See also FT-38, FT-40, FT-42, FT-45, FT-47, FT-52, FT-56 and FT-58. See also FT-57.

2 *Change in Processing Procedure for Physicians and Dentists "Selling" Candidates*—a Attention is invited to FT-56, May 1, 1943, paragraph 3. It was there announced that, with the approval of the Surgeon General and the War Manpower Commission, the procurement procedure for physicians and dentists whose "availability clearance" forms were received from state Procurement and Assignment chairmen in California, Connecticut, Massachusetts, New York or Wisconsin had been changed so as to permit this service to try to "sell" such individuals on their patriotic duty to take steps to qualify for a commission.

b The Procurement and Assignment Service, War Manpower Commission, has announced that, effective at once, this "selling" program is authorized to be carried on by Officer Procurement Service with respect to physician and dentist candidates declared "available" in all states in which physicians and dentists, respectively, will be procured in 1943 as indicated in FT-34, paragraph 3a (1), (2) and (3), and paragraph 3b.

3 *Appointment of Interns*—a Attention is invited to FT-34, paragraph 2b. To provide for the establishment of a uniform policy for the appointment of Medical School graduates, the Secretary of War has directed:

"Appointments of individuals as first lieutenants, Medical Corps, Dental Corps or Veterinary Corps, respectively, in the Army of the United States may be made on recommendation of the Surgeon General on completion of their academic training at an approved medical, dental or veterinary school without reference to paragraph 7i, section II, AR605-10, Dec. 30, 1942."

b The purpose of this direction is to enable the appointment of medical school graduates prior to the completion of their period of internship, although they may not be called to active duty until completion of such period of internship. See the first proviso to paragraph 16i, OPS Manual for Procurement of Officers (revised through April 15, 1943).

BRITAIN TURNS OVER HOSPITAL TRAIN TO U. S. ARMY

A hospital train of six ward cars and a car for sitting up patients with a capacity of about 300 wounded has been turned over to the U. S. Army Medical Department in Great Britain, the first such train built there for the United States. This "reverse lend-lease project" was formally handed over on March 25 to Brig. Gen. Paul R. Hawley, U. S. Army Medical Corps.

CAPTAIN BROWNING DECORATED

The War Department has announced the award of the Silver Star to Capt James L. Browning, U. S. Army, formerly of Iron Mountain, Mich. for gallantry in action at Guadalcanal. The award was made by Lieut. Gen. Millard F. Harmon, commander of the U. S. forces in the South Pacific area. The citation reads "James L. Browning, captain, Medical Corps, United States Army for gallantry in action on Jan. 10, 1943 at Guadalcanal. At the point of exhaustion from a hard overland march, Capt. Browning cared for the wounded far into the night and performed surgery which saved many lives. These duties were performed under constant machine gun fire. Due to overexertion from long hours of work, it was later necessary for Capt. Browning to be evacuated to the rear." Captain Browning later on January 13 was wounded in action also. He was then returned to the homeland, where he is now recovering at Nichols General Hospital, Louisville, Ky.

RECIPROCAL MEDICAL ARRANGEMENTS
FOR CANADIAN AND UNITED
STATES SOLDIERS

Reciprocal medical arrangements have been made for Canadian and American soldiers whereby personnel of the U. S. armed forces while on duty, leave or furlough in Canada who cannot obtain medical or dental treatment from the United States facilities in Canada will receive free such treatment as is necessary for immediate requirement from the Canadian medical and dental services. If treatment or hospitalization will exceed thirty days, arrangements will be made for transfer, where possible, to the United States. Canadians in the armed forces in the United States who require medical or dental attention will report to the nearest U. S. naval or army hospital, the nearest veterans hospital or Veterans Administration office or to the nearest medical representative of the Veterans Administration. If none of these facilities are immediately available, the Canadian personnel will be admitted to civilian hospitals in the United States. The Canadian legation in Washington will be notified and bills for treatment will be forwarded to the Surgeon General of the U. S. Army, Washington, D. C. Officers of the U. S. Army admitted to Canadian hospitals will pay \$1 a day subsistence while patients.

ARMY PERSONALS

Brig. Gen. James S. Simmons, M. C., director of the Preventive Medicine Division, Surgeon General's Office, delivered the commencement address on March 21 at the graduation exercises for Washington University Schools of Medicine, Dentistry and Nursing in St. Louis. The title of the address was "New Horizons in Military Medicine."

The President has been authorized in Senate Bill 872 to appoint Frank T. Hines for many years administrator of the U. S. Veterans Bureau to be a brigadier general in the Army of the United States after which he would be placed on the retired list of the Army. General Hines held that rank before resigning to become head of the U. S. Veterans Bureau.

Col. Walter S. Jensen, M. C., executive officer in the Office of the Air Surgeon, delivered the annual Edwin J. Jarecki Memorial Lecture at Philadelphia on April 29.

MINIMUM EQUIPMENT FOR MEDICAL
OFFICERS ORDERED OVERSEAS

The following list of equipment for officers ordered overseas was prepared by Major Albert L. Delaney of the Halloran General Hospital, Staten Island, New York, in collaboration with Major Norman J. Pike, M. C., and Captain David A. Hornby, M. C.

The first thought of an officer ordered to overseas duty is "What in the nature of personal equipment, shall I take?" This will depend in a large measure as to whether you are to go by air or by water. Having traveled both ways, I have listed a minimum that, under most conditions, may be considered a minimum.

First, set your house in order. Execute a power of attorney to one you trust to handle your affairs in your absence. Blank forms for this can be had from the Adjutant General's representative at your camp.

Secondly, make the necessary allotments. Arrange your insurance, both government and private.

Next your will. Owing to differences in state laws, consult a competent lawyer from your home state and have him write the will.

"Keep your mouth shut." This applies from the time you get your orders until you are discharged. Impress your family that you cannot tell them anything and therefore they are not to ask.

Now we come to equipment.

- 1 Bed roll. Get an air mattress if you can. Do not get kapok. I had one and threw it away.
- 2 Caps. Two field caps (one winter and one summer) and one garrison.
- 3 Blouse. One.
- 4 Pants. Two olive drab wool and two cotton khaki. Pinks optional.
- 5 Socks. Six pair cotton or wool. I favor light wool, as this absorbs perspiration.
- 6 Shoes. One pair dress shoes, one pair general issue shoes. (Be sure to carry one box of shoe polish.)
- 7 Shirts. Two olive drab wool (not pink or dark green) three cotton khaki.
- 8 Tie. Two regulation type.
- 9 Insignia. Three full sets.
- 10 Field jacket. One wool lined.
- 11 Raincoat. One good one, not a trench coat.
- 12 Overcoat. One olive drab, not the dress coat.
- 13 Underwear. Six shorts, six undershirts. Two sets should be wool.
- 14 Handkerchiefs. Six.
- 15 Sweater. One wool pull over type, preferably khaki.
- 16 Razor blades. Ten packages.
- 17 Soap. Four bars.
- 18 Shaving soap. One cake, not tubes or jars. Cakes do not squish.
- 19 Tooth powder. One can. Cans do not squish.
- 20 Mirror. One medium size.
- 21 Housewife. Be sure to have about six needles, black, white, khaki thread.
- 22 Cigaretts. Four cartons.
- 23 Towels. One face, two bath.
- 24 Watch. General issue or your own, but it must keep accurate time.
- 25 Knife. Pocket, one good one.
- 26 Tool kit. A small leather kit is on the market which weighs about 8 ounces and has a hammer, screwdriver, corkscrew and pair of pliers, each of which fits onto a heavy knife handle. It certainly helps.
- 27 Cigaret lighter. One.
- 28 Cigaret lighter fluid. One can.
- 29 Cards playing. Two packs.
- 30 Money. \$100 average, not more than \$150.
- 31 Writing material. One tablet, one package of envelopes.
- 32 Sunglasses. Optional. If you get them, get good ones costing \$5 to \$10.
- 33 Radio set. Leave it at home.
- 34 Games. Use your judgment, but usually, no.
- 35 Ball of stout twine.
- 36 Pan rubber. This is on the usual list, but don't take it. Use your helmet. Helmet can be used to scrub up for an emergency operation incidentally.
- 37 Gloves. Regulation only, one pair.
- 38 Camera. Banned by regulation. Many army personnel have them. Must take your own films.
- 39 Footlockers. I understand these are on the way out. Use a barracks bag. If you told your clothes carefully, the barracks bag works fine.
- 40 Handbag. Get a volpack type bag. This carries a world of stuff, keeps creases in the trousers and is not heavy. The type issued by the Air Corps has a stiffener in it and this takes up too much room and weight. Get the loose ones. Carry your musette bag. Don't ever let it get away from you. In it carry an extra shirt, change of socks and underwear, one handkerchief and your last orders.
- 41 Keep all your orders in one place and fastened together.
- 42 Keep your pay data card and Adjutant General's Office identification card with you at all times.
- 43 Use the V-mail rather than a regular letter.
- 44 Atlas. One small one, but good one on maps. Optional, but gives a lot of arguments.
- 45 Nails. One small can of assorted sizes as old as 5 and 10 cent stores.

Just two cautions. First, don't buy a lot of trinkets as soon as you land. Wait until you learn to balance United States costs against those of the country you are in. Second, Doctor, hunt cover during an attack. The Red Cross bracelet on your arm cannot be distinguished from a plane or by an exploding shell, nor is it respected by a Jap.

No attempt has been made to discuss organization equipment as a parting word, travel light and you will rest more comfortably.

NAVY

MALARIA FIGHTERS IN CONSTRUCTION
BATTALIONS

The U S Navy started courses in malaria control for the training of medical officers and hospital corpsmen at the Navy Medical School Bethesda Md, as soon as the war in the Pacific began, and malaria control units are now a part of all naval and marine forces in war zones in which malaria is present. These units comprise malinologists, entomologists, sanitary engineers and hospital technicians. Now the Naval Construction Battalions which accompany combat forces have organized malaria control groups within their own battalions, thus providing 110 trained men to fight malaria the moment a construction battalion moves in. A chief petty officer and nine other petty officers all especially trained in malaria control in addition to their regular Seabee training head parties of 10 carefully selected and well trained men each, whose duty it is primarily to eradicate sources of malaria infection. These men, however, are part of the regular construction battalion and when not engaged in malaria control take part in other work.

The training of Seabee men for malaria control which is carried out at Camp Peary, Va includes among other things instruction in draining, spraying and ditching and in individual precautions against malaria. The prevention of malaria in men landing in an infected tropical area begins with the wearing of head nets and gloves the use of mosquito repellents and the taking of quinine or atabrine. The spraying of huts, and tents, screening of shelters and the segregation of infected natives done when possible.

Rear Adm. Ross T. McIntire, Surgeon General of the Navy, considers, the *Army and Navy Journal* of May 1 says, that

malaria is the most serious medical problem of the war. Admiral McIntire has emphasized the need of the navy for medical officers who are skilled in the treatment and prevention of malaria. Commanding officers in tropical areas consider that tools and equipment for malaria control are almost as important as ammunition and food. The Secretary of the Navy, Frank Knox, has directed all navy unit commanders to give disease control priority in operations in tropical combat zones in keeping with the military situation. The Navy has recommended to all medical schools that emphasis be placed in their instruction on the study of tropical diseases, particularly for those students who plan to enter the navy medical corps.

NAVY PERSONALS

Lieut. Howard P. Rome (MC) USNR, has been assigned to the psychiatric section of the Bureau of Medicine and Surgery and Lieut. (jg) Albert Eskin (MC) USNR, to temporary duty in the correspondence course section of the Bureau of Medicine and Surgery.

Lieut. Vernon L. Anderson, Dental Corps, USN, formerly dental officer on the U S S *Hasp*, addressed the New York State Dental meeting at Syracuse, N Y, May 18-20, on "Combat Experiences."

Lieut. Comdr S. A. Isquith (MC) USNR, who recently returned from fleet duty, has been detailed as technical adviser to the section of Audio Visual Education, Division of Preventive Medicine, in the production of an instructional motion picture on personal hygiene.

CIVILIAN DEFENSE

SHOES FOR NURSES' AIDES

Nurses' aides needing nurses' shoes can obtain them even though they have spent stamp 17 if there are no unused stamps available from members of their families, the Office of Civilian Defense announced on April 28. The Office of Price Administration outlined its policy as follows: "The need for special work shoes for nurses' aides has been recognized, and they have been given the same privileges as graduate nurses and other persons who require special shoes necessary for the performance of their jobs. To acquire nurses' white shoes, a nurses' aid must first use her stamp 17. If she has none and no stamps are available from a member of her family, she may apply to her local board for special shoe stamp (on OPA Form R-1703). The use of her stamp or the stamp of a member of her family for such white shoes will not prevent her from acquiring shoes for general wear if she has none or has only one pair and needs two pairs. She may make further application to her board for the shoes needed for general wear in such a case." Nurses' aides are members of the United States Citizens Defense Corps of Civilian Defense who volunteer for hospital duty and are trained under the auspices of the American Red Cross.

PLAN FOR EMERGENCY MEDICAL
SERVICE IN INDUSTRIAL
PLANTS

In a new bulletin the Medical Division of the Office of Civilian Defense recommends that every plant medical department should prepare a "disaster operations plan" to provide medical service in case of a plant catastrophe involving large numbers of casualties. The new bulletin outlines arrangements which should be made to assure adequate medical care at such times.

The War and Navy Departments urge that plants for which they are responsible plan to use the facilities of the Emergency Medical Service organized by Civilian Defense authorities. The Medical Division has in turn urged that local Chiefs of Emergency Medical Service assist plant medical departments by

placing the community medical facilities at their disposal in the event of a major emergency, regardless of its cause.

The disaster operations plan should provide for necessary first aid care at the site of the incident, for adequate ambulance service, and for hospitalization of the seriously injured. Provision must first be made for casualty stations. Several sites should be selected. An additional site outside the plant should be selected for use in the event of extensive damage to the plant.

The importance of identification and records is especially emphasized. The bulletin points out that in any disaster confusion will be inevitable and that it will be difficult, without adequate records, to identify the seriously injured and the dead and to determine the number and names of the missing. The uninjured as well as the injured should be accounted for. A record should indicate the places to which the injured have been taken.

The bulletin recommends that arrangements be made with the local Chief of Emergency Medical Service to insure that ambulances under his direction be made available to the plant should a disaster involve the entire community. Any ambulance facilities owned by the plant should be made available to the local Chief if they are not required at the plant.

Present plans for the hospitalization of industrial accident victims are likely to be inadequate in the event of a major catastrophe. To provide quick and efficient service to injured persons, casualties should be distributed among various hospitals. Arrangements must be made with the local Chief of Emergency Medical Service for the admission of casualties to community hospitals, all of which will be under his supervision during a major emergency.

The plan of mutual aid between a plant and a community requires a definite understanding that members of the Emergency Medical Service will be admitted promptly to a plant in an emergency. Personnel investigated and approved by the Service Command will receive identification cards from the Office of Civilian Defense. The bulletin also outlines the program of federal compensation for injuries to Civilian Defense workers.

MISCELLANEOUS

MEDICAL MISSION TO VISIT RUSSIA

Lieut Col LOVELL DAVIS, Chicago, professor of neurologic surgery at Northwestern University, according to the Chicago *Sun* has been named to a six man Anglo-American medical mission to visit Russia. Since Colonel Davis's arrival in London September 6 of last year he has been senior consultant on neurosurgery in the European theater. Another American member of the mission to Russia will be Col Elliott C Cutler of Brigham Hospital, Boston and professor of surgery at Harvard Medical School. Colonel Cutler is senior consultant on general surgery to the American expeditionary force.

MILITARY CASUALTIES AND ACCIDENTS
AMONG WORKERS

The National Safety Council Chicago, stated on April 27 that casualties to the U S armed forces since Pearl Harbor had been 12,123 dead, 15,049 wounded and 51,063 missing or prisoners, a total of 78,235. These figures are from the latest report of the Office of War Information, released on April 24. Casualties to American workers through accidents since Pearl Harbor had been 64,500 dead and 6,000,000 injured, on and off the job. The Council offers the comparison as evidence that accidents still are helping the Axis by draining America's manpower. The total American accident toll workers and others, since Pearl Harbor is 128,000 killed and about 13,000,000 injured, the council said. Among the victims were thousands of skilled workers and key men in the nation's war program. "This huge waste of manpower on the home front is more alarming than ever before," said Ned H Dearborn, executive vice president of the council, "in view of the fact that the nation is taking increasingly drastic steps to mobilize every available ounce of manpower to insure victory. It is little enough to ask every American to be extra careful these days. No war worker is so unimportant that he can afford an accident."

REGISTRATION OF NURSES IN CANADA

Mrs Rex Eaton, assistant director of national Selective Service, has announced the result of the registration of graduate nurses carried out by the Canadian Selective Service at the middle of March. A total of 50,455 nurses registered. Registration figures by provinces are as follows: Prince Edward Island and Nova Scotia 3,364, New Brunswick 1,948, Quebec 7,758, Ontario 23,497, Manitoba 2,033, Saskatchewan 2,740, Alberta 3,369, British Columbia 5,744, Yukon 2.

The registration somewhat exceeds the number of graduate nurses thought to be available in Canada. The results will now be made available by Selective Service to the Canadian Nurses Association, at whose request the registration was taken, and also to the Medical Procurement and Assignment Board, which is making a survey of available health services.

THE FOOD RATIONING ORDER

According to Mr Archie M Palmer, associate director Food Rationing Division Office of Price Administration, General Rationing Order No 5 is in the process of revision to give hospitals a more equitable allotment of food for patient requirements. Group III of the general rationing order in which hospitals were placed received a point factor of only 0.6 while institutions of involuntary confinement in group II received 1.2, or twice as much. The hospital Bureau of Standards and Supplies Inc, New York, believe that a point factor of not less than 2.6 is required. While it is believed that the point factor allowed for patients meals will be substantially increased hospitals should endeavor to meet their requirements as best as they can under the present order until such a revised order is issued and should file immediately form R-315 for additional allotments required for patients. In most instances it is believed that the local boards will grant a request for additional amounts of processed food when the hospital is able to show that the types of food requested are essential to patient welfare.

that the amounts asked for are reasonable, and are based on the following considerations: "That only the rationed foods requested will serve the purpose because, while from a dietary standpoint unrationed foods may be substituted, such substitutes are not available, or (2) they are not within the hospital's budget, or (3) they require additional help or special equipment which is not available to prepare them."

PUBLIC HEALTH UNDER HITLER

Lozr List, Sarajevo, of January 28 stated that the Velika Supa of Hum in Mostar has sent a circular to Vrhbosna, stating inter alia: "In order to isolate the epidemic of spotted typhus which recently broke out in Mostar and the neighborhood, the municipal health authorities, conjointly with the military authorities, have prohibited access to all persons coming from Sarajevo who are not supplied with a health certificate issued by a doctor confirming that the person concerned is free from spotted typhus has passed twenty-one days in quarantine and has been vaccinated. This certificate must be confirmed by the chief German army doctor in Sarajevo."

According to DNB (for Europe) of January 15, German official sources drew attention to a disease affecting their armies in Russia. This "plague of Eastern Europe," it is stated, is called "Volhynian fever"—Volhynia being a part of the Western Ukraine—and it was already dreaded by the soldiers in the East during the last war, who styled it "trench fever." It is an epidemic disease the prevention of which is of the greatest importance for the conduct of the war in the East.

The symptoms of this disease vary, but there are always violent attacks of fever, which are accompanied by strong pains in the legs and also in the arms, the head and other parts. From the beginning of the campaign in the East, German medical research has been striving with all means to combat this mysterious disease. These experiments have now met with success and given surprising results, for it has been shown that this "Volhynian fever" is related to malaria. When this plague of Eastern Europe was treated with the well known German malaria cures "atebrin" and "plasmochin," in almost all cases the fever and pains disappeared.

The Swedish newspaper *Nya Dagligt Allehanda* says that Norwegian hospitals are crowded to the bursting point partly because of the ruthless requisitioning of them by the Germans and partly because of increasing illnesses.

According to the dispatch, skin diseases especially are showing an alarming increase. Syphilis, which was previously rare in Norway, is now a common phenomenon and prostitution is widespread. Diphtheria epidemics rage in several places, especially in the Opland districts. Most of the hospitals in Norway have been requisitioned by the Germans and as a result sick Norwegians must be treated in schools, meeting halls and similar buildings under conditions which were abandoned a hundred years ago.

In a recent edition of the Swedish newspaper *Arbetaren* it is reported that German authorities have begun forcibly to draft Norwegian nurses for German hospitals in Norway. According to an Oslo report eighty nurses from Akers hospital who now serve at the temporary Norwegian hospital in Berg's school must go to German hospitals to replace German nurses who have recently been sent back to Germany, where there is a shortage of nurses in the overcrowded hospitals.

Dr Leonardo Conti, Nazi health leader writing in the German newspaper *Die Volkische Beobachter* on the tasks and successes of the German state controlled health organization made the following claims for his organization:

These are the statistics that he presented. There are at present 1,100 health offices with roughly 12,600 doctors established by the National Socialist state. Another 1,100 doctors are employed by labor authorities and a further 670 doctors by the German Labor Front. Three thousand doctors are attending to the Hitler Youth. There are 1,300 special offices, fighting venereal diseases and tuberculosis. Mother and child organizations have at present in all 63,000 advisory offices at their disposal.

ORGANIZATION SECTION

OFFICIAL NOTES

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled "Before the Doctor Comes" is on the air Thursday afternoon at 2:15. Mrs. June Merrill interviews Dr. W. W. Bauer, Director Bureau of Health Education on common home health problems. The last program which is entitled "Immunization" will be broadcast on May 27.

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at

5 p. m. Eastern War Time (4 p. m. Central War Time, 3 p. m. Mountain War Time, 2 p. m. Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transmission at 10:30 p. m. Saturdays over Station WMAQ.

The titles and guest speakers for the last four programs are as follows:

May 29 "Sick Call"

Speaker: Brig. Gen. John M. Willis, M. C., U. S. Army, Commanding General, Camp Grant, Illinois

June 5 "Doctors for Tomorrow"

Speaker: Brig. Gen. Fred W. Rankin, M. C., U. S. Army, President of the American Medical Association

June 12 "Medical Discoveries in Wartime"

Speaker: Dr. Morris Fishbein, Editor of THE JOURNAL

June 19 "Doctors at War: Report to America"

Special program being arranged. To be announced later.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S. 897 has been reported to the Senate, proposing an amendment to the Insecticide Act so as to provide that any white powder insecticide or fungicide containing arsenic in its elemental form or in any of its combinations or fluorine in any of its combinations, shall unless deemed unnecessary by the Secretary of Agriculture, be considered to be adulterated unless it is distinctly colored in accordance with regulations promulgated by the Secretary of Agriculture. The reported bill exempts from the coloring requirement substances sold for manufacturing or noninsecticidal or nonfungicidal uses. H. R. 2664 has passed the House, a bill to provide for the training of nurses for the armed forces, governmental and civilian hospitals, health agencies and war industries, through grants to institutions providing such training. This legislation will cease to be in effect on the date of the termination of hostilities in the present war as determined by the President or on such earlier date as the Congress by concurrent resolution or the President may designate, except for certain purposes of adjustment with respect to nurses undergoing training at the time of the termination of hostilities.

Bills Introduced—The President has submitted to Congress supplemental estimates of appropriation for the United States Public Health Service in the amount of \$307,700 (H. Doc. 200). Of this, \$219,000 will be used, it is contemplated, for the pay of commissioned officers and \$88,700 for the furnishing by the Public Health Service to and at the request of any federal department or independent establishment of coordinating and consultative services with respect to methods and standards for operating emergency health facilities in such department or establishment, including in-service training of such health facilities personnel, and providing employees of such agencies (1) tuberculosis and psychiatric examinations and (2) health and nutrition instruction through lectures and demonstrations. S. 1096, introduced by Senator Bailey, North Carolina, proposes to establish a Bureau of Vital Records in the United States Public Health Service and to transfer thereto the functions of the Division of Vital Statistics of the Bureau of the Census. The bill also authorizes an appropriation of \$2,000,000 for each fiscal year to assist states and their political subdivisions to establish and maintain adequate vital record services. H. R. 2669, introduced by Representative Maas, Minnesota, proposes that retired enlisted men of the Army, Navy, Marine Corps and Coast Guard, including members of the Fleet Reserve, shall be entitled to dispensary treatment in any Army or Navy hospital. Where hospitalization is indicated, the bill provides, such retired enlisted men shall be entitled to hospitalization

without cost in either Army or Navy hospitals. H. R. 2679, introduced by Representative Chapman, Kentucky, provides that all provisions of existing law and regulations applicable to veterans of World War I be extended to include veterans of the present war and their dependents. H. R. 2703, introduced by Representative Rankin, Mississippi, provides more adequate and uniform administrative provisions in veterans' laws pertaining to compensation, pension and retirement pay, payable by the Veterans' Administration. H. R. 2706, introduced by Representative Kunkel, Pennsylvania, provides for the promotion of officers of the Medical Administrative Corps of the Regular Army to grades up to and including that of colonel.

STATE MEDICAL LEGISLATION

Alabama

Bills Introduced—S. 22 proposes to require the state board of health to formulate a plan for the care and treatment of indigent persons suffering from cancer and to establish and designate standard requirements for the organization, equipment and conduct of cancer clinics or departments in general or private hospitals, or private clinics of the state. The state board of health would also be required to formulate and put into effect an educational plan for the purpose of preventing cancer throughout the state of Alabama, aiding in the early diagnosis of cancer, and informing hospitals and cancer patients of the proper treatment. S. 40 proposes to require any person who the health officer has probable cause to believe has a venereal disease or has been exposed to a venereal disease to be examined for a venereal disease by the health officer or some other reputable physician. In the event that such person refuses to undergo such examination, he would be committed to a county or city jail on order of the county health officer and detained there until, in the judgment of the health officer, he is no longer a source of danger to the public health. S. 47 proposes to make it unlawful for a person to conduct, maintain or operate an ambulance unless such ambulance is under the immediate supervision and direction of a person holding a first aid certificate or a person legally authorized to engage in the practice of medicine in Alabama. It would further be unlawful for any person to conduct, maintain or operate an ambulance which does not contain and carry with it as a part of its regular equipment a first aid kit or box approved by the American Red Cross and traction splints of a character approved by the American Red Cross. A first aid certificate is defined by the proposal as being one issued by the United States Bureau of Mines or

by the American Red Cross wherein it is stated that the person to whom it is issued has successfully completed the required training and met the established standards of one of such organizations. S 64 proposes to require all persons between the ages of 14 and 50 residing or living in the state of Alabama to have a blood examination for syphilis by an approved laboratory test. H 22 proposes to define a general hospital as a hospital or sanatorium that maintains a daily average of 10 or more patients and where general medicine, general surgery, dietetics, obstetrics and the care and nursing of infants and children, and such other subjects as the board may deem advisable, are practiced and taught.

California

Bill Introduced—A 1287, to amend the education law, proposes to authorize boards of education to grant health and development certificates to persons holding a certificate of registration as an audiometrist issued by the state board of public health, proposes that the qualifications of an otologist shall be a physician's and surgeon's certificate and a health and development certificate, proposes that the qualifications for an audiometrist shall be a certificate of registration as an audiometrist issued by the state board of public health and a health and development certificate and proposes that no otologist or audiometrist shall be employed or permitted to supervise the health and physical development of pupils unless he holds a health and development certificate.

Colorado

Bill Enacted—H 196 was approved, April 19. It provides that a person who has actually resided in the state for three or more years, who is suffering from tuberculosis in any form requiring treatment and who is without sufficient means to obtain it, may be furnished such treatment out of the tuberculosis fund of the county of the recipient's residence.

Connecticut

Bill Enacted—S 562 has become chapter 194 of the Laws of 1943. It authorizes a town board of education to appoint one or more legally qualified practitioners of medicine as school medical advisers and to provide such medical advisers with adequate facilities to provide for public health examinations of individual pupils. It further requires each pupil enrolled in the public schools to have a health examination either by a legally qualified practitioner of medicine or by the school medical adviser, at least once every three years to ascertain whether such pupil is suffering from any physical disability tending to prevent him from receiving the full benefit of school work and to ascertain whether such school work should be modified in order to prevent injury to the pupils or to secure for the pupils the best education results. Each physician making such examination shall sign each form containing the record of the examination made by him and shall make his recommendations concerning the pupil in writing.

Florida

Bills Introduced—S 286 proposes that no license to marry shall be issued to any male or female person in the state of Florida unless such person presents a health certificate showing freedom from any communicable disease. S 306 proposes the establishment and creation of an institution of higher learning to be known as the University of South Florida, which shall be a state university and shall have as its primary purpose a school of medicine and a school of dentistry and such other departments as may from time to time be determined on and added thereto by the state board of control and state board of education. The proposal would further provide that the school of medicine and school of dentistry should be first class medical and dental schools and should be maintained and operated in accordance with the standards of education approved by the American Medical Association and the American Dental Association. S 367 proposes the creation of a Florida board of massage to examine persons desiring to practice massage defined as the art of body massage, either by the hand or by mechanical apparatus, oil rubs, gymnastics, colon irrigations, hot and cold packs, cabinet baths (excluding fever therapy), tub shower sitz and similar baths. H 377 provides, among

other things, that in an action at law in which the mental or physical condition of a party is in controversy the court in which the action is pending may order such person to submit to a physical or mental examination by a physician, the order to be made only on motion for good cause shown and on notice to the party to be examined and all other parties, and to specify the time, place, manner, conditions and scope of the examination and the name of the person by whom it is to be made.

Bills Enacted—S 139 was approved, May 1. It requires any physician or other person who makes a diagnosis in, or treats a case of, venereal disease to make a report thereof to the state board of health or to the local health officer and to make a further report in the event that such person ceases reporting to the physician prior to his having become cured or rendered noninfectious. S 141 was approved May 1. It requires all persons rejected or deferred for military service who are infected with venereal disease to report to venereal disease clinics operated by the state board of health and to take treatment either from a private physician or at public expense for such venereal disease.

Illinois

Bill Introduced—H 577 proposes the creation of special educational facilities for educable mentally handicapped children and proposes further that no child shall be eligible for such special education except on the recommendation of or with the approval of a qualified psychologic examiner, defined to mean a person who has graduated with a master's or higher degree in psychology or educational psychology from a higher institution of learning which maintains equipment, course of study and standards of scholarship approved by the Superintendent of Public Instruction, who has had at least one year of full time supervised experience in the individual psychologic examination of children, or a character approved by the Superintendent of Public Instruction and who has such additional qualifications as may be required by the Superintendent of Public Instruction.

Maryland

Bills Enacted—S 360 has become chapter 724 of the Laws of 1943. It provides that no person shall sell, dispense or give away any drug or medicine for the treatment or cure of venereal disease or any sulfonamide drug except on the written prescription of a physician licensed to practice medicine. Such prescription not to be refilled except on order of said physician. H 53 has become chapter 311 of the Laws of 1943. It amends the insurance code by exempting from the provisions thereof any policy or contract granting solely and exclusively hospitalization insurance. The prior law exempted any policy or contract issued by a nonprofit association. H 76 has become chapter 963 of the Laws of 1943. It repeals that section of the licensing law providing that no county, city or other political subdivision of the state shall require a license to transact any business or occupation which is required to obtain a state license and creates a new section providing that no county, city or other political subdivision of the state shall require any person, firm or corporation to obtain a permit or license to transact any business or occupation for which it or he is required to obtain a state license, nor shall any county, city or other political subdivision of the state levy any occupational tax or fee on such person, firm or corporation for transacting any such business or engaging in any such occupation for which such state license is required except where such tax is necessary for regulatory purposes in the interest of the public health, safety or morals. H 644 has become chapter 600 of the Laws of 1943. It places certain limitations on advertising by persons practicing medicine and surgery.

Massachusetts

Bills Introduced—S 456 proposes that no female employee shall be dismissed by her employer on account of pregnancy. S 470 proposes to amend the existing law providing that any license, permit or certificate of registration issued by any department, division, board, commission or officer that expires while the holder thereof is serving in the military or naval service of the United States may be renewed within six months after the termination of such service by providing that no fee shall be charged or collected for the period between the expiration of the certificate and the renewal thereof.

Minnesota

Bill Enacted—H 303 has become chapter 633 of the Laws of 1943. It amends the workmen's compensation act by redefining the word "accident" so as to include "occupational disease" defined as a disease peculiar to the occupation in which the employee is engaged and due to causes in excess of the ordinary hazards of employment, a disease arising out of and in the course of the employment. H 1239 has become chapter 649 of the Laws of 1943. It amends the law requiring the licensing of any hospital, sanatorium, rest home, nursing home or other institution for the hospitalization of human beings by bringing within the purview thereof all such institutions as are operated by the state, county or local government or any department, board or agency thereof.

Missouri

Bill Introduced—S 154 to amend the workmen's compensation act proposes that nothing in the act shall prevent an employer from taking the compensation he may be entitled to thereunder and also maintaining a civil action against any physician or surgeon for malpractice.

New Hampshire

Bill Enacted—H 32 has become chapter 166 of the Laws of 1943. It provides enabling legislation for the incorporation of non-profit sharing organizations formed for the purpose of establishing, maintaining and operating a nonprofit medical service plan whereby medical service may be provided at the expense of said corporation by physicians to subscribers to said plan under contract entitling such subscribers to certain medical service. The law sets forth the form of contract, method of fixing rates and contracts approved, method of financing such plans and certain restrictions among which is the provision that no medical service corporation shall impose any restrictions on physicians who administer to its subscribers as to methods of diagnosis or treatment. The law also provides that no person shall become a participating physician unless he shall be a physician holding a full license to practice medicine in the state of New Hampshire.

New York

Bill Enacted—A 1923 has become chapter 691 of the Laws of 1943. It amends the mental hygiene law by eliminating therefrom the existing requirement that the head of the department be a reputable physician with at least ten years' experience in the actual practice of his profession and at least five years' actual experience in the care and treatment of persons afflicted with mental disease in an institution for their care and treatment. In lieu thereof it provides for the appointment of a medical director who shall be a reputable physician, a graduate of an incorporated medical college, with at least ten years' experience in the actual practice of his profession and at least five years' actual experience in the care and treatment of persons afflicted with mental disease in an institution for their care and treatment. The duties of the medical director are to advise with the commissioner on all matters affecting medical policy within the department, have direct charge and control, under the general departmental direction of the commissioner, of medical administration, care and treatment, and of medical and nursing personnel, and perform such other duties in the place and stead of the commissioner as may be lawfully assigned to him.

Ohio

Bill Introduced—H. J. R. 47 proposes a resolution which would require the submission to the voters of a proposal to amend the state constitution so as to prohibit the levying of an excise tax on the sale or purchase of drugs or medicines prepared or sold by a registered pharmacist in accordance with or under a lawfully issued prescription.

Bills Enacted—H 112 was approved, April 29. It amends the law relating to osteopaths by providing for one osteopathic member of the medical examining board and requiring osteopaths to be examined by such board in the subjects of anatomy, physiology, pathology, chemistry and diagnosis, surgery, obstetrics and such other subjects as the board may require and by

the osteopathic member in the subjects of materia medica and therapeutics and the principles and practice of osteopathic medicine. Successful applicants will be entitled to practice osteopathy and surgery. Persons now licensed to practice osteopathy but who have not passed an examination before the state medical board will be allowed to continue to practice osteopathy and minor and orthopedic surgery but not to practice major surgery. H 142 was approved, April 26. It provides that no person shall operate an institution for the care of persons suffering from a communicable disease or persons adjudged to be mentally ill, feeble-minded, epileptic or insane within 2,000 feet of any public, private or parochial school.

Oklahoma

Bill Enacted—S 98 was approved, April 12. It authorizes a physician legally qualified to practice in the state of Oklahoma to perform a postmortem cesarean section when the physician has reason to believe that the child is viable in the mother. In the performance of such operation, the physician shall not be liable either civilly or criminally, though performed without the consent of those in whom the law has recognized a legal right of the possession of the body of the deceased, provided the operation be performed in good faith and with due skill and without unnecessary injury or mutilation. The law further provides, however, that the operation shall not be performed over the protest of those in whom the law has recognized a legal right to the possession of the body of the said deceased.

Rhode Island

Bills Enacted—S 177 was approved, April 28. It amends the law relating to cash sickness insurance by exempting from the provisions thereof employees who adhere to the teachings of any church, sect or denomination and depend for healing on prayer or spiritual means in the practice of religion. H 533 was approved, April 22. It provides for the creation of a special commission to be known as the Special Rhode Island Public Health Laws Survey Commission, to make a comprehensive reexamination and survey of the public health laws of the state and municipalities thereof and to make recommendations for the complete modernization of those laws in keeping with the most recent innovations and tried practices of other states. Such recommendations must be made in legislative form not later than April 12, 1943. H 591 was approved, April 22. It provides for the creation of a board of examiners of electrolysis, defined as the removal of, or preventing the growth of, the hair on any part of the human body by means of electrical apparatus. H 937 was approved, April 27. It amends the basic science law by providing that any person who on April 27, 1940 was pursuing a course of study in any of the healing arts in a professional school then approved by the division of examiners in the department of health, but who had not previously completed at least one year of preprofessional collegiate education and training in an accredited academic college and who was at the time of entrance into such professional school a legal resident of Rhode Island and who can meet all the other requirements provided by this act, shall be eligible for examination by the basic science board. H 946 was approved, April 22. It requires any physician who discovers that a patient between the ages of 4 and 16 is suffering from deafness or shows indications of being or becoming hard of hearing to report immediately his findings, together with the name and address of such child, to the director of health along with such other information as the director may require.

Wisconsin

Bills Introduced—S 305, to amend the law relating to medical aid to old age assistance recipients, proposes that medical, hospital, surgical and dental aid or Christian science treatment to a beneficiary may in the discretion of the county pension department be authorized and paid for directly to the person or firm furnishing such care. A 611, to amend the law relating to the licensing of nurses, proposes the addition thereto of conditions and requirements for the licensing of "licensed attendants" who would be authorized to perform simple procedures in the physical care of a patient and such other procedures as may be directed by the attending physician.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Dr Tainter Joins Winthrop Company—Dr Maurice L. Tainter, since 1935 professor of pharmacology at Stanford University School of Medicine and since 1934 professor of pharmacology and head of the division of physiologic sciences, College of Physicians and Surgeons, School of Dentistry, San Francisco has been named research director of the Winthrop Chemical Company, Inc. Dr Tainter will make his headquarters at the company's plant and laboratories in Rensselaer, N. Y. In making the announcement, Dr Theodore G. Klumpp, president of Winthrop, stated that Dr Tainter's appointment implements the policy of research expansion by Winthrop. Dr Tainter was born in Carroll, Iowa, in 1899. He graduated at Stanford in 1925. Prior to assuming his professorship at Stanford he served successively as assistant in pharmacology, instructor, assistant professor and associate professor. He has written many scientific papers and is the editor of the *Stanford Medical Bulletin* and a member of the editorial board of *California and Western Medicine*.

Public Health Meeting—A public health conference of the Southern California Public Health Association will be held at the Pasadena Civic Auditorium May 24. Among the speakers will be Dr John L. Rice, New York, on 'War-time Trends in Public Health'; Dr Karl F. Meyer, San Francisco, 'Problems Relating to Communicable Disease Control'; and Nathan Sinai, D.P.H., Ann Arbor, Mich., 'Medical Care During the Emergency and Postwar Periods'. A round table discussion on 'Methods of Solving Present and Future Public Health Problems' will be conducted by Dr Robert Hughes Parry, Bristol, England, Dr Rice, Dr Edith P. Sappington, San Francisco, Dr Don W. Gudakunst, New York, Dorothy Deming, R.N., Dr Sinai, Dr Wilton L. Halverson, San Francisco, Dr Albert S. McCown, Washington, D.C., and Raymond H. Greenman of the American Social Hygiene Association, Washington, D.C. Dr Parry will discuss 'Organization of a City's Health and Medical Services Against Air Raids' at the evening session and Dr McCown 'The American Red Cross in a War-Torn World'.

DISTRICT OF COLUMBIA

Annual Scientific Assembly—"Medical Progress Since Pearl Harbor" will be the theme of the fifteenth annual scientific assembly of the Medical Society of the District of Columbia to be held at the Mayflower Hotel, September 30-October 2. Dr Harry H. McNitt, Washington, is general chairman of the committee on arrangements.

The Davidson Lecture—The Medical Society of the District of Columbia announces that the seventh Davidson Lecture is to be given October 13. Physicians and scientists who wish to compete for the privilege of being the lecturer are asked to submit an essay to the secretary of the society not later than July 1. In case no essay is found worthy, the subcommittee will declare no award and the lecturer will then be selected by the full executive board of the society.

GEORGIA

Member of State Board Honored—Robert Foster Maddox, member of the state board of health for twenty-nine years and chairman for twenty years, was honored at a recent meeting of the board when, in recognition of his services, his fellow members presented a portrait of him to the state of Georgia to be hung in the library of the Georgia Department of Public Health. The picture was accepted on behalf of the state by Dr Thomas F. Abercrombie, Atlanta, state director of public health.

Outbreak of Smallpox—The state department of public health announced that an outbreak of 9 cases of smallpox in a single county in northeastern Georgia was recorded recently. The source was traced to a person visiting in the home of a relative. The relative became ill while visiting at a friend's house and for some time was unaware of the nature of his illness. Of the 8 persons who subsequently contracted the disease, 3 were members of the family he was visiting and 5 had either visited him during his early illness or had been in contact with those who had.

ILLINOIS

District Meeting—The annual meeting of the Iowa and Illinois Central District Medical Association will be held at Rock Island on May 27. The speakers will include Major Lindon Seed, M.C., A.U.S. on 'Use of Intravenous Fluids and Blood', Dr Italo F. Volini, Chicago, 'Clinical Observations on Heart Disease,' and Dr Charles F. McKhann, Ann Arbor, Mich., 'Progress in the Control of Communicable Disease'.

Chicago

Dr Fernel in Trouble Again—A criminal information was filed April 29, by U.S. Attorney J. Albert Woll charging Dr. Jean Paul Fernel, former self-styled plastic surgeon, with violation of the Federal Food, Drug and Cosmetic Act of 1938, the *Chicago Tribune* reported. The information alleges interstate shipments of food and drugs which were misbranded. The newspaper reported that Federal Judge Philip L. Sullivan fixed bond for Dr. Fernel at \$2,500. Dr. Fernel's license to practice medicine was revoked in 1938.

Mayor Requested to Appoint a Noise Commission—The appointment by the mayor of a municipal noise commission was requested on May 7 by the City Club of Chicago in a letter sent to Mayor Kelly by Herman L. Ellsworth, president of the club. The noise abatement committee of the club, headed by Thomas H. Coulter, is applying itself to the problem of noise reduction and, with the cooperation of the city administration, is endeavoring to enlist the help of all citizens in the elimination of unnecessary noise. With the declaration by the mayor of Chicago's participation in National Noise Abatement Week, May 30-June 5, the city will compete for the awards given each year by the National Noise Abatement Council, to that city in each of four population groups which submits on or before July 1 the most convincing evidence of accomplishment in the elimination of unnecessary street noise and in the control of noises in industry, offices and the home during the period of June 7, 1942 to June 5, 1943.

New Alcoholic Service—A special alcoholic service was recently opened at the Chicago State Hospital. The unit consists of 20 beds to be used for patients of a special type in whom the prospect of rehabilitation is especially good, the majority of beds to be available for patients who give prospect of benefiting from the Alcoholics Anonymous technique. A small number of beds will be available for patients who will receive the "conditioned reflex" treatment. Every effort will be made to keep these two separate functions of the alcoholic ward distinct from each other. The program is similar to one which has been carried out at the Manteno State Hospital, Manteno, Ill. Members of the Alcoholics Anonymous will select a special committee to carry on the program. They will select the cases to be treated, but the hospital will reserve a right to veto such nominations should they exceed the number to be handled or should they appear to be the wrong type of patient. The office of Alcoholics Anonymous is at 209 South State Street. Any patient who is not suitable for the special treatment in the special alcoholic service but who is in need of state mental hospital care because of mental illness can be committed through the usual court procedures in any of the nine Illinois state hospitals located at Elgin, Kankakee, Manteno, Peoria, East Moline, Jacksonville, Alton, Anna and Chicago.

INDIANA

Gift Provides New Department of Pediatrics—The late George Wesley Longworth and his wife Emma Dennis Longworth, Fort Wayne, have provided for a gift of \$63,000 to the new Parkview Memorial Hospital, Fort Wayne. The money will be used for the children's department and will include a section embracing a wing of the third floor to be known as the George Wesley and Emma Dennis Longworth Department of Pediatrics. The proposed Parkview Memorial Hospital will cost \$800,000 and will replace the present Methodist Hospital. Fort Wayne newspapers reported.

KENTUCKY

Management of Gonorrhea—Dr Percy S. Pelouze, assistant professor of urology at the University of Pennsylvania School of Medicine, Philadelphia and consultant for the gonorrhea control program for the U.S. Public Health Service, opened a series of lectures in Louisville May 3 on the management and treatment of gonorrhea. Dr Pelouze will spend the month of May in Kentucky, speaking at various places throughout the state.

MASSACHUSETTS

Boston Floating Hospital Admits Paying Patients—

The board of trustees of the Boston Floating Hospital recently ruled that the hospital can now admit patients to the wards who are able to pay part of their hospital costs. As a result, the administrative officers of the hospital are working out a plan whereby all patients admitted will be allowed to pay whatever they are able toward these costs. During the early years of its existence, when the hospital was maintained entirely by private funds, an endowment fund was accumulated. In 1929-1930 when the New England Medical Center was formed funds from the campaign were used mostly in erecting the present building of the Boston Hospital, in remodeling and refurnishing parts of the old Boston Dispensary and in the erection of an additional building of five stories, three of which are used by the Boston Dispensary for clinics and laboratories and two of which are used by the hospital to house the nurses. The hospital is the outgrowth of the barge *Chifford* which in the summer of 1894 made five excursions into Boston Harbor taking aboard mothers and their sick babies and children. After a day's outing they were returned to shore in the late afternoon. The following year the barge was purchased and daily trips were made. In 1896 the boat became a real hospital, as in addition to the people who were taken for the daily cruises permanent wards were established, physicians were aboard and a training school for graduate nurses was begun. In 1906 a boat designed as a hospital ship was built. This served as the Boston Floating Hospital until the boat was burned in 1927. During this time in addition to the outing for the babies from the crowded sections of Boston work in the study of infectious diarrheas of infants was done aboard the boat. Following the burning of the boat in 1927 it was decided not to rebuild the hospital ship. Sometime later the Boston Floating Hospital became associated with the Tufts College Medical School and the Boston Dispensary to form the New England Medical Center. In 1931 the present building of the Boston Floating Hospital, located adjacent to the enlarged and remodeled Boston Dispensary, was opened. During the time the hospital ship was maintained and during the early years of its on-shore activity the Boston Floating Hospital was entirely charitable in that no patients were admitted to the hospital who could afford to pay anything for their care. Four years ago a 4 bed semiprivate ward was opened in the hospital to which private patients and semiprivate ward patients could be admitted.

MICHIGAN

Alumni Clinic Day—The annual Alumni Clinic Day of Wayne University College of Medicine was held at the Horace H. Rackham Educational Memorial Building, Detroit, May 12, with the following speakers:

Dr. Fredrick F. Yonkman, Detroit, Doctors and Drugs on the Civilian Front

Dr. John J. Prendergast Jr., Detroit, Medical Problems of the War Workers and Their Management in Your Practice

Dr. Oliver Cope, Boston, Use of the Latest Methods in the Treatment of Burns with Experience Gained from the Boston Night Club Fire

A panel discussion was held on "Problems and Recommendations Concerning the Hospitalization of Your Patient." In the evening, with Dr. Patrick L. Ledwidge, Detroit, toastmaster, Harold E. Stewart, Ph.D., department of geography at Wayne, spoke on "Geopolitical Aspects of American Security."

NEBRASKA

Symposium on Obstetric Analgesia and Anesthesia—The department of obstetrics and gynecology of the University of Nebraska College of Medicine, Omaha, will present a symposium on obstetric analgesia and anesthesia at the University of Nebraska Hospital, Omaha, May 28. Among the speakers will be:

Dr. Frank W. Hartman, Detroit, Tissue Changes Observed Under Deep Sedation and Anoxemia

Robert A. Hingson Jr., passed assistant surgeon, U. S. Public Health Service, Continuous Caudal Analgesia and Anesthesia in Obstetrics

Dr. Norman R. Kretschmar, Ann Arbor, Mich., The Obstetrician's Point of View of Analgesia and Anesthesia

Dr. Arthur H. Parmelee, Oak Park, Ill., The Pediatrician Looks at Obstetric Analgesia and Anesthesia

A session entitled "Painless Labor, Please" with Dr. Earl C. Sage, Omaha, as the moderator will be handled by the speakers participating in the symposium.

NEW YORK

Actions Taken at State Meeting—Dr. Herbert H. Bankus, Buffalo, was chosen president-elect of the Medical Society of the State of New York at its annual meeting in Buffalo on May 4 and Dr. Thomas A. McGoldrick, Brooklyn, was installed as president. The society adopted a resolution urging that citizenship be made a requisite for licensing as a doctor in New York State. Another resolution, which pointed out that "the problems of food in this country, as well as the world at large, are the concern of the medical profession," urged the American Medical Association to request representation at the United Nations Food Conference. The house of delegates of the society also urged the board of regents to "limit the number of examinations that may be taken by any candidate for licensure to practice medicine to three in all" and to refuse to admit "to examination for licensure any graduate of a foreign medical school 25 or more per cent of whose graduates, taking the examination during the past ten years, have failed to pass." Other resolutions adopted urged that the director of the bureau of workmen's compensation be appointed by the state society on a full time basis at a salary of \$15,000 a year and "unreservedly condemning and repudiating all unethical activities under the workmen's compensation law." The society also voted unanimously to appoint a committee to formulate a long range program "providing medical care for all, under the leadership of the medical profession." The new committee will be known as the Planning Committee for Medical Policies and will have "wide powers to study all phases of economic matters affecting the profession and the public, including provision for the rehabilitation and the reconstruction of individuals now in the community or returning from war service." The committee will consist of six members appointed by the speaker of the house of delegates, the president, the president-elect, the secretary, the speaker and the chairman of the board of trustees or a member of the board designated by him.

New York City

Academy Given Goldsmith Collection—Mrs. Lesta Ford Clay recently gave the New York Academy of Medicine a collection of more than one hundred editions of the *Vicar of Wakefield* by Oliver Goldsmith in memory of her father, Dr. Linsley R. Williams, a former director of the academy. The collection has been on display in the library of the academy of medicine.

Dr. Urey Awarded Franklin Medal—Harold C. Urey, Ph.D., professor of chemistry at Columbia University, received the Franklin Medal, April 21, for his discovery of an "isotope of hydrogen of mass 2 which has resulted in the opening of new fields of knowledge in three of the physical sciences." The presentation was made at the annual medal day ceremonies of the Franklin Institute, Philadelphia.

Dr. Sheehan Named Acting Dean of New York University—Dr. Donald Sheehan, professor of anatomy at New York University College of Medicine, has been named acting dean during the absence of Dr. Currier McEwen, who has been granted leave as dean to serve as a lieutenant colonel in the medical corps of the Army of the United States and executive officer of the Bellevue Hospital Affiliated Unit, the First General Hospital. Dr. Clarence E. de La Chapelle, professor of clinical medicine at New York University, will act as assistant dean in place of Dr. John Mulholland, who was granted a military leave last October to take charge of the surgical service of the Bellevue Unit.

TEXAS

Special Society Election—Dr. Titus H. Harris, Galveston, was elected president of the Texas Association for Mental Hygiene at a recent meeting with the Texas Social Welfare Association in Dallas. Other officers are Robert L. Sutherland, Ph.D., Austin, and Talma W. Buford, Minter, vice presidents, and Miss Lucile Allen, Dallas, secretary-treasurer.

Field Workers Examined for Tuberculosis—Migrant field workers who seek employment in Michigan and neighboring states are being given x-ray examinations in Dallas and San Antonio in offices which were opened on April 1. The bureau of tuberculosis control of the Michigan Department of Health, Lansing, has been supervising this program for the past five years in an effort to prevent the entry of tuberculous workers into Michigan and neighboring states. Most of the persons who are examined in the Texas office of the bureau are naturalized Mexicans living in Texas.

VIRGINIA

Dr Perrow Dies—Mosby Garland Perrow, Ph.D., director of the Lynchburg Department of Public Welfare and the Lynchburg Bureau of Public Health, died suddenly on February 26, aged 66, of cerebral hemorrhage. Dr Perrow received his degree of doctor of philosophy in 1908 from Washington and Lee University, Lexington.

Personal—Anthony J. Borowski, Dr. P.H. until recently chief of the health section of the Federal Works Agency, Works Progress Administration, Washington, D.C., has been appointed chief clerk and statistician of the division of records and statistics of the Richmond Department of Public Health.—Dr William Dandridge Haden, who has not been in active practice for a number of years, recently retired from the civic life of Charlottesville where he had served three terms as mayor and twelve consecutive years as a member of the city council.

WEST VIRGINIA

State Venereal Disease Project—Camp Fairchance in Boone County, which has been in operation for several years as a camp for underprivileged children, has been designated as a venereal disease center by the state department of health and will be converted into a hospital just as soon as federal funds are available. Establishment of the center for the treatment of venereal disease among prostitutes was authorized by the 1943 legislature. Under the act, prostitutes from any county in the state may be confined for treatment. Dr Clifton F. McClintic, Charleston state health commissioner, has made application under the Lanham Act for \$200,000 a year for the operation of the new center. The program has the full support of the War Department and the U.S. Public Health Service.

GENERAL

Meeting Canceled—The annual meeting of the American Gynecological Society which was to be held in Hershey, Pa., May 31-June 2, has been canceled because of the difficulties of wartime travel.

Meeting of Ophthalmologists—The seventy-ninth annual meeting of the American Ophthalmological Society will be held at The Homestead, Hot Springs, Va., June 10-12. Among the speakers will be:

- Drs. Sanford R. Gifford, Irving Puntenney and John G. Bellows: Chicago. Notes on Keratoconjunctivitis Sicca.
Dr. Conrad Berens and Edith L. Nilson: New York. Relationship Between the Bacteriology of the Conjunctiva and Nasal Mucosa. Especial Reference to Certain Extraocular Inflammatory Diseases.
Dr. Jonas S. Friedenwald, Dr. Heinz Herrmann and Robert Moses: Baltimore. The Distribution of Certain Oxidative Enzymes in the Ciliary Process.
Drs. John V. Evans and Eli Jefferson Browder: Brooklyn. Problem of Split Macula. A Visual Field Study.
Drs. Grady E. Clay and James Mason Baird: Atlanta, Ga. Ophthalmoscopic Classification of Hypertensive Diseases.
Drs. Lawrence T. Post and Theodore E. Sanders: St. Louis. Temporal Arteritis. Case Report with Eye Findings.
Dr. Algernon B. Reese: New York. The Significance of Pigment Freckles on the Iris Associated with Malignant Melanoma of the Uvea.
Dr. Placidus J. Leinfelder: Iowa City. Choked Disks and Low Intracranial Pressure Occurring in Brain Tumor.

Society of Clinical Pathologists—The annual session of the American Society of Clinical Pathologists will be held at the Drake Hotel, Chicago, June 3-6, under the presidency of Dr. Harry Goldblatt, Cleveland, whose address will be entitled "The Clinical Pathologist as an Experimenter." Among the speakers will be:

- Drs. George R. Dochat and James W. Kernohan: Rochester, Minn. Prognosis in Carcinoma of the Stomach Based on Dukes-Broders Combination of Grading.
Dr. George H. Hansmann and Marion Tully: Milwaukee. Cat Bite and Scratch Wounds with Consequent Pasteurella Infection in Man.
Drs. Horace M. Banks and Harold F. Dunlap: Indianapolis. Case of Sarcoidosis.
Dr. Harry J. Corper and Maurice L. Cohn: Ph.D. Denver. The Virulence of Tubercle Bacilli and the Fallacy of Assuming the Grade of Virulence from Arbitrary Designations.
Drs. Frank W. Hartman and Harvard L. Romence: Detroit. Liver Necrosis in Burns.
Dr. Morris Fishbein: Editor THE JOURNAL. Trends of Medical Practice in the Postwar Period.

Special features will include a symposium on cirrhosis of the liver on Saturday and a tumor seminar on Sunday. Dr. Max M. Strumlin, Bryn Mawr, Pa., will discuss "The Role of Plasma Transfusion in Medical Problems Not Related to the State of Shock." The paper was chosen by the general research committee of the society as the Ward Burdick Award Contribution for 1943.

Central Source of Information on Infantile Paralysis—The National Foundation for Infantile Paralysis is, with the cooperation of other agencies developing the only complete central authentic source of information on infantile paralysis in the world. A complete bibliography of all scientific literature that ever has been published pertaining to infantile paralysis is being compiled by the foundation and is expected to be ready for publication in book form in the early part of 1944. The first volume will contain a record of all scientific material on poliomyelitis published in the world up to the end of 1943. Subsequently the data will be kept up to date by publication of annual supplements. Brief abstracts of the more important articles will be included in the bibliography to be published by the foundation. The collection will serve to acquaint research workers with investigative work that has already been carried out and will make available complete information pertaining to the disease, including articles published in any language. Data which were assembled by the International Committee for the Study of Infantile Paralysis organized by Jeremiah Milbank in 1928 and assembled in the library of the New York Academy of Medicine, has been turned over by the academy to the National Foundation for inclusion in the new publication. The committee, which is now extinct, collected data pertaining to all literature on poliomyelitis that had been published up to 1932. The compilation of the information is being carried out for the foundation with the aid of the library of the American Medical Association and the John Crerar Library, both in Chicago, under the direction of Dr. Morris Fishbein, Editor of THE JOURNAL, and Dr. Ludwig Hektoen, Chicago, editor of the Archives of Pathology. Assisting in carrying out the work in Chicago is Miss Ella Salmonsén, medical librarian of the John Crerar Library.

CANADA

The Jackson Memorial Lecture—Philip Bard, Ph.D., professor of physiology, Johns Hopkins University School of Medicine, Baltimore, delivered the annual Hughlings Jackson Memorial Lecture at the Montreal Neurological Institute April 28. His subject was "Representation as a Principle of Central Nervous Organization."

LATIN AMERICA

Personal—Dr. Victor Fernandez Manero, chief of the Federal Department of Health in Mexico, Mexico City, was recently presented with the diploma and the gold medal or a fellow honoris causa of the International College of Surgeons as a token of national appreciation for his work on public health in Mexico.

Educational Exhibit for Museum of Hygiene—The Cleveland Health Museum of which Dr. Bruno Gebhard is director, has completed a nineteen piece educational exhibit for the National Museum of Hygiene, Mexico City. The display includes all models of the Cleveland Museum's original traveling exhibit "Food for Health" and in addition new displays on digestion, dentistry, circulation and tuberculosis control. It was prepared at the instigation of Dr. Gustavo Uruchurtu A., director of general health education of the department of public health of Mexico City on the recommendation of Dr. Manuel Urrutia, director of the National Museum of Hygiene of Mexico, during his internship at the Cleveland Health Museum. The Mexican exhibit is entirely in Spanish.

Deaths in Other Countries

Albert Grant Fleming, Montreal, Que., Canada, University of Toronto Faculty of Medicine, 1907, Strathcona professor and chairman of the department of public health and preventive medicine and formerly dean of the faculty, McGill University Faculty of Medicine, fellow of the American Public Health Association and in 1938 vice president, served as president of the Canadian Public Health Association in 1935, appointed secretary of the health insurance committee of the British Columbia College of Physicians and Surgeons in 1905, joined the city health department of Toronto as bacteriologist and later director of medical services including the medical and dental inspection of school children, served as medical officer in the armed forces of Canada during World War I, in 1921 became deputy medical health officer of Toronto, member of the board of health of the city of Montreal, medical director of the Bell Telephone Company of Canada, received the doctor of public health degree from the University of Toronto in 1914, aged 55, died April 9 in the Montreal Neurological Institute of brain tumor.—**Dr. Antonio Cardoso Fontes**, formerly director of the Instituto Oswaldo Cruz, Rio de Janeiro, died March 27, aged 63.

Warning on Use of Warmth for Treatment of Shock

In the *Army Medical Bulletin* the warning is given that the enthusiastic application of heat for shock has inherent risks. The blood volume nearly always diminishes after severe injuries, because fluid has left the vessels either by hemorrhage or by oozing into damaged tissues or both. The consequent fall in blood pressure brings into play a vasoconstrictor mechanism which raises pressure by reducing the capacity of the vascular bed. It is not yet certain which parts of the vascular system are affected by this vasoconstriction, but undoubtedly the cutaneous circulation is much diminished and its capacity is considerable. Even in a normal person warming may increase the blood content of the skin by as much as a pint. When the superficial vessels are already constricted far more than a pint may be brought to the surface and diverted from vital functions. Hence excessive warming may interfere with the body's endeavor to restrict its total vascular capacity and make a little go a long way. It may also accelerate loss of fluid from the surface by evaporation and sweating, it may accelerate metabolism of skin and muscle and thus jeopardize structures whose blood supply is impaired by local injury, and it may promote autolysis of damaged tissues and absorption of autolytic products. Experimentally it has been shown that general and vigorous heating of injured animals decreases their chance of recovery and hastens their end. The application of cold, on the other hand though it lengthens their period of survival, does not increase their chance of recovery. Thus theory and experiment agree that casualties should be warmed in a conservative manner with blankets and hot water bottles applied after removal of wet clothes. More potent means of heating, such as a heat cradle, may be used when blood volume is being, or has been, restored by transfusion. But the heat should never be so great as to cause sweating, and limbs with injured blood vessels or gangrene should not be warmed at all. As far as the "cold" of shocked patients is compensatory, it is a symptom that should not be treated energetically unless its cause—reduction of blood volume—can be treated at the same time. Whereas warming plus transfusion gives excellent and prompt results, warming alone may be carried too far and lead to vasodilatation, circulatory collapse and death.

The Water Problem in Shipwreck

The Medical Research Council has issued "A Guide to the Preservation of Life at Sea After Shipwreck," which naval officers and physicians cooperated in producing. Advice is given with regard to everything which can arise, including routine preparations and precautions in the ship, abandoning ship, procedure in the lifeboat, lifeboat ailments, treatment of the sick and wounded, steps toward rescue and treatment after rescue. It is pointed out that water is more important than food. Masters who have appreciated its importance have improvised as much as 120 gallons per boat. The ration of water depends on the likelihood of being picked up. If this is not likely to happen for a week, no water need be given in the first twenty-four hours unless the men have been sweating from hot weather or exhaustion. The ration recommended is 18 ounces per man daily, which should be continued until there is 1 pint per man in hand. The ration must then be reduced to 2 ounces daily. The experience of survivors suggests that moistening the lips and washing the mouth with sea water are helpful and also that small quantities of sea water can be used for soaking

biscuits. But large drafts of sea water cause death, and even small amounts may prejudice the chances of survival. Permission to drink sea water, therefore, should never be given. Rectal administration does not relieve thirst and is harmful. Every drop of rain water should be collected, and no vessel which can hold water should be thrown away. Pools of water formed on melted ice or on ice floes, provided they are not brackish from salt water spray, may be drunk. The drinking of urine is harmful and should be forbidden. When water rations are low, the food rations should consist mainly of fats, starches and sugars and should contain little protein.

Rehabilitation and Resettlement of the Disabled

The Emergency Medical Service was established by the government for the treatment of casualties from air raids among the civilian population, which were expected on a scale much greater than occurred. This led to a great interest in rehabilitation. In January 1942 the minister of labor and national service announced that the government had decided to prepare as soon as possible comprehensive measures for the rehabilitation, training and resettlement of disabled persons generally. An exhaustive report by a committee of government officials appointed to consider the subject has just been published. It states that rehabilitation of a person disabled by injury or sickness is not solely a medical problem. When restoration in the medical sense is achieved, the services of the social and industrial expert are required, first, to determine in consultation with medical experts whether the patient can return to his previous occupation and, if not, what other occupation would be most suitable (for which there should be training facilities) and, second, to insure that the restored capacity is used to the best advantage. Thus there is a transfer of responsibility from the medical to the industrial services, but the latter should begin to operate before the former ends. A notable step to this end is the linking for the first time of the hospitals and the employment exchanges. This will be assisted by the continuation into the postwar period of the specialized centers for particular types of disability adopted by the Emergency Medical Service.

Under the emergency service twenty-one orthopedic centers have been established, about half of which are permanent orthopedic hospitals carrying on their peacetime functions in addition to emergency work. There is a full range of facilities, including occupational therapy and workshops. There are sixty hospitals under the emergency scheme for fractures at which these facilities are available but not in such a complete form.

Sir St Clair Thomson

Sir St Clair Thomson, who has been described as the Nestor of the British school of laryngology, has died at the age of 83 years as the result of an accident. He was trained in laryngology at the famous school of Vienna by Schotter, Stoerk and Hajek, as well as by the otologist Politzer. In his old age Hajek fell a victim to Nazi persecution. Like many others, neither his age nor his eminence saved him. He became an exile in England and it was a pleasure to Thomson to repay his debt to his teacher by welcoming and acclaiming him in laryngologic circles. In 1893 Thomson settled in London and was appointed physician to the Throat Hospital, Golden Square. In 1905 he became physician in charge of the department of laryngology and in 1908 professor at King's College. But in 1903 he was attacked with tuberculosis of the larynx and was probably the first patient in this country to carry out the treatment of complete silence. This was one of the two diseases, the other being cancer of the larynx, to which he devoted the greatest attention. For the latter he did much to establish the operation of laryngofissure. His technique was followed all over the world. In 1927 he showed at the Royal Society of Medicine four physicians on whom he had performed this operation. They were all active in their profession. He taught that

properly carried out the operation should be free from danger. In 1910 he reported the first case in this country of removal of a straw pin, with the aid of endoscopy, from a secondary bronchus. An excellent teacher and writer his textbook *Diseases of the Nose and Throat*, first published in 1911, became famous. In 1937 a fourth edition appeared in which he was assisted by Mr V. E. Negus. He published many papers on various subjects of his specialty and was the European editor of the *Laryngoscope*. A cultured man of great personal charm and an accomplished linguist, he was in demand at international congresses, where he often served as an interpreter. At the International Medical Congress held in London in 1913 he was president of the section of laryngology and was able to welcome the members of each national group in their own language. He was corresponding honorary member of most of the laryngologic societies of the world. He was president of the Laryngological Section of the British Medical Association three times. In 1926 he was presented with a loving cup by 175 of his fellow laryngologists, which perhaps pleased him most of all his distinctions. He then said that he had two ambitions—to till to the best of his ability the small corner of the field of medicine in which he worked and to have the esteem and possibly the affection of his fellow workers. He attained both ambitions in the fullest degree.

Surgery of the Aged

Surgery of the Aged was discussed in the Medical Society of Basel by Prof. Dr. F. Merke who said that the progressive overaging of the population makes it necessary for physicians to concern themselves more with the diseases of old age. Even though the forecasts made by mathematicians and statisticians for coming decades might be doubted, they nevertheless are to a certain extent correct with regard to the present trends in age distributions of populations. In the last three decades, populations have shown a tendency to become overaged. Internists have for some time given more attention to geriatrics. Surgeons too have given it more attention recently. To obtain a picture of the risk of surgical interventions in old patients a survey was made on all persons over 60 who were operated on at the St. Clara Hospital in Basel. The total number was in excess of 800. It was hoped that the survey would reveal whether the risk is really as much greater as is often assumed, even among physicians. The following factors were ascertained. In a group of the most severely threatened patients with gastric carcinoma resection actually has a relatively high mortality risk. Ten fatalities occurred in 29 resections (34.5 per cent). In these cases tumor cachexia is added to the physiologic weakness of old age which further reduces the resistance. The risk involved in the resection of gastric ulcer is slightly less in these old patients. Whereas the mortality was only 4.7 per cent in 105 ulcer resections in patients less than 60 years old it reached 20 per cent in 15 who were over 60 years old. Of course these were especially severe cases, that is ones in which simple gastroenterostomy would have been altogether insufficient. Acute appendicitis, contrary to the opinion of some authors is not as rare in the aged as is often assumed. Extensive statistics from England and America reveal that from 1 to 2 per cent of all attacks of acute appendicitis occur in persons over 60 years of age. The mortality is given as between 20 and 50 per cent. The Mayo clinic reports a mortality of 16 per cent in 82 cases. The author's own observations involve 44 cases with a mortality of 18 per cent. In mammary carcinoma (50 cases over the age of 60) the mortality was only 8 per cent. In 53 struma resections in patients over 60 in whom the operation was as a rule not performed for cosmetic reasons but on account of severe tracheal com-

pression or substernal strumas or because of relapses in exhausted or hypertensive persons, the mortality was 5.7 per cent. Prognosis was favorable in femoral and umbilical hernias as long as these were not incarcerated. There was not a single fatality in 29 nonincarcerated hernias in persons between 60 and 85 years of age, only 3 incarcerated hernias terminated in death. The prognosis is exceptionally good for nonincarcerated inguinal hernias: not a single fatality occurred in 60 patients between 60 and 89 years of age, in 12 incarcerated inguinal hernias in patients of the same age there was 1 death of gastric hemorrhage.

It is important to know that in the presence of tumor cachexia and in urgent operations on the aged the risk of operation is actually greater but that in nonurgent operations and in the absence of other severe defects there is no increased risk for aged persons, and such patients can be subjected to surgical intervention with a calm conscience. Careful preliminary treatment, anesthetization and after-treatment are prerequisites for good results.

Epidemic Poliomyelitis

According to investigations of the Swiss health authorities, the collecting depots had all together 16 liters of convalescent serum. The Children's Clinic of the University of Basel no longer is one of these collecting depots because it prefers to call convalescents whenever the need arises and to obtain fresh serum. The clinic has on file the addresses of a large number of persons, many of them in the immediate vicinity.

The Swiss Health Office recently published statistics on the morbidity and fatality of epidemic poliomyelitis in Switzerland for the years 1931 to 1941. The detailed statistical statements showed the following results:

Year	Number of Cases	Fatalities	Percentage of Lethality
1931	351	58	16.5
1932	123	27	22.0
1933	198	28	14.1
1934	80	17	21.2
1935	245	46	18.8
1936	1,269	121	9.5
1937	1,494	177	11.8
1938	283	39	13.8
1939	521	53	10.2
1940	237	34	14.3
1941	1,479	149	10.0

Marriages

KENNETH GRAHAM LAWRENCE, Florence, S. C. to Miss Jewell Oneida Simmons in Nashville, Tenn., March 27.

THOMAS KIMBALL SLAUGHTER JR., Greenville, S. C., to Miss Mildred Marian Grout of Memphis, Tenn., April 13.

THOMAS GORSUCH REED, Lake Odessa, Mich., to Miss Geraldine Meyer of St. Petersburg, Fla., April 5.

NATHANIEL CLAYTON EWING to Miss Mary Virginia Kennedy, both of Charlottesville, Va., April 8.

JULES VICTOR JR., Savannah, Ga., to Miss Leonora Carolyn Huguenin at Beaufort, S. C., April 11.

BERNARD KYLE MUNDI, Baltimore, to Miss Marjorie Jane McKee of Chanute, Kan., March 25.

THOMAS WILLIAM TALBERT to Miss Dorothy Bramlette both of Columbia, S. C., March 26.

ROBERT ALBERT GREER RICKETSON to Miss Alma Allen Huth both of Durham, N. C., April 14.

LANNEAU DURANT LIDE JR. to Miss Ruth Easterling Bethea both of Marion, S. C., March 27.

VIOLET M. CRABBE to Mr. Gerald Forbes both of Wolcott, Ind., at Wabash, January 28.

PALL HARMON HARMON, Safford, Pa., to Miss Dorothy Ann Ross in Chicago, March 20.

JOHN FLETCHER COVER to Miss Bettie Thomson both of Birmingham, Ala., recently.

WARREN S. TUCKER to Dr. Mary Alice Craig both of Indianapolis, February 21.

Deaths

James Ewing * New York, famed in the field of cancer research and in 1941 recipient of the Distinguished Service Medal of the American Medical Association, died at the Memorial Hospital for the Treatment of Cancer and Allied Diseases May 16, aged 76.

Dr. Ewing was born in Pittsburgh on Christmas Day, 1866. He received his bachelor's degree from Amherst College in 1888 and his master of arts degree in 1891, the same year in which he was awarded his degree of doctor of medicine at the College of Physicians and Surgeons of New York now known as Columbia University College of Physicians and Surgeons. Later many honorary degrees were conferred on him.

Dr. Ewing served at Columbia from 1893 to 1897 as a tutor in histology, held the Clark Fellowship from 1896 to 1899, and taught as instructor in clinical pathology from 1897 to 1898. From the following year until 1932 when he became professor of oncology, he was professor of pathology at Cornell University Medical College.

In 1931 when the January issue of *Annals of Surgery* was published to commemorate his sixty-fourth birthday, James Ewing was said to be "likewise the foremost American investigator of the entire group of neoplastic diseases." This volume was subsequently republished as a book by Lippincott under the title "Cancer." In recognition of his productive activities in the field of cancer, notable honors have been paid to Dr. Ewing, the Mickle Fellowship in 1935, the John Scott Medal in 1936, the Clement Cleveland Medal in 1940. He had been a member of numerous scientific groups, including the Philadelphia Pathological Society, the Academy of Medicine of Brazil, Swedish Roentgen Society, Academy of Medicine of Budapest, National Academy of Sciences, Association of American Physicians, American Roentgen Ray Society, American Medical Museums Society, American Association of Pathologists and Bacteriologists (president, 1906), Society of Experimental Biology and Medicine (president 1912), New York Academy of Medicine, New York Pathological Society and the American Association for Cancer Research (president 1907, vice president 1936), advisory council to the American Society for the Control of Cancer (vice president, 1922) created in 1937 to act as a clearing house for information and to integrate and coordinate the activities of the major cancer organizations in the United States, Harvey Society (president, 1908), American Radiological Society, National Advisory Cancer Council and advisory committee to the New York state division of cancer control. He was delegate to the International Congress of Cancer in Madrid in 1933. In 1932 Dr. Ewing became medical director of Memorial Hospital for the Treatment of Cancer and Allied Diseases, in full charge of all departments and activities, where, for a number of years, he has also been director of cancer research. At various times he had delivered such notable lectures as the Frank Billings Lecture, the Beaumont Lectures, the R. W. Stewart Memorial Lecture, the Janeway Lecture and the Citizens Aid Society Memorial Address.

Dr. Ewing was chairman of the Section on Pathology and Physiology of the American Medical Association, 1916-1917, and, since 1926, had been a member of the editorial board of the *Archives of Pathology*. The citation accompanying the Distinguished Service Medal of the Association stated that the honor was "in recognition of his long and distinguished service as an investigator and teacher, his significant contributions to medical literature, and his successful inspiration of young inves-

tigators in the field of medical science." Dr. Ewing was a prolific contributor to the literature, his best known book being "Neoplastic Diseases." The volume is considered a landmark in the literature on cancer. Other notable writings include "Clinical Pathology of the Blood," published in 1900, and his "Textbook on Legal Medicine," published in 1910.

Mont Rogers Reid * Cincinnati, professor of surgery in the University of Cincinnati College of Medicine, member of the Committee for the Protection of Medical Research of the American Medical Association, died at his home, May 11, aged 54, of coronary thrombosis.

Born in Oriskany, Va., April 7, 1889, Dr. Reid received his bachelor of arts degree from Roanoke College, Salem, Va., in 1908. He graduated at Johns Hopkins University School of Medicine, Baltimore, in 1912. After completing his internship, Dr. Reid filled various staff positions at Johns Hopkins Hospital and at the medical school. In 1922 he went to the University of Cincinnati Medical School as associate professor of surgery, becoming Christian R. Holmes professor in 1931. Later he was named director of the surgical service at Cincinnati General Hospital and Children's Hospital and consultant at the Hamilton County Tuberculosis Hospital.

Dr. Reid was a first lieutenant in the medical corps of the U. S. Army during World War I.

In 1934 Dr. Reid was given the first presentation of the Rudolph Matas Medal for vascular surgery for his experimental work in systemic effects of arteriovenous fistulas and his other studies on the peripheral circulation. He was a fellow of the American College of Surgeons and a member of the American Surgical Association (vice president, 1934-1935), Southern Surgical Society, International Surgical Association, Society of Clinical Surgery, American Association for the Advancement of Science, Society of University Surgeons, Central Surgical Association, National Advisory Cancer Council, director of the American Society for the Control of Cancer and a member and honorary member of numerous other societies and national fraternities.

In 1926, after a year as visiting professor of surgery at the Peiping Union Medical College, Peking, China, Dr. Reid participated in an Asiatic expedition

in Mongolia conducted by Roy Chapman Andrews. He had written numerous articles in current publications and in 1929 prepared a chapter on surgery of the sympathetic nervous system in the Dean Lewis System of Surgery.

Dr. Reid was recognized as a brilliant surgeon, his achievements as a student and teacher gave him a renown for leadership in his chosen field.

Frederick Theodore Van Beuren Jr. * New York, Columbia University College of Physicians and Surgeons, New York, 1902, associate clinical professor of surgery at his alma mater and formerly associate dean and secretary, specialist certified by the American Board of Surgery, member of the American Surgical Association, fellow of the American College of Surgeons, served during World War I, member of Squadron A, New York National Guard, from 1899 to 1910, when he resigned as captain, first lieutenant in the medical reserve corps of the U. S. Army from 1910 to 1918 and later a major, in 1935 elected a member of the board of directors of the Morristown (N. J.) Library, assistant attending surgeon to the Lincoln Hospital from 1910 to 1913 and the Roosevelt Hospital from 1913 to 1921, attending surgeon to the Volunteers' Hospital from 1915 to 1917 and the Sloane Hospital for Women for many years, associate visiting surgeon, Presbyterian Hospital, consulting surgeon to the Elizabeth A. Horton Memorial Hospital, Middletown, for many years, president of the Morristown (N. J.) Memorial Hospital, where he died March 13, of pneumonia, aged 67.

JAMES EWING, M.D., 1866-1943

David Chester Brown ☼ leader in the development of the Committee on Scientific Exhibit and for many years a member of the House of Delegates and the Board of Trustees of the American Medical Association died at his home in Danbury Conn., May 12, aged 79, of coronary thrombosis cerebral hemorrhage and general arteriosclerosis.

Dr Brown was born in Norfolk Va. Nov 16 1863. After graduating at Yale University School of Medicine New Haven Conn. in 1884 Dr Brown pursued postgraduate work at Hartford Hospital and the Universities of Berlin and Prague engaging in the private practice of medicine at Danbury in 1886. In 1907 he became a member of the House of Delegates of the American Medical Association serving until 1914 and again from 1916 to 1918. He was a member of the Board of Trustees from 1918 until 1934. In 1922 after the Board of Trustees of the Association took over the Scientific Exhibit Dr Brown was appointed a member and chairman a position he held until 1934. He was a fellow of the American College of Surgeons had once been president of the Connecticut State Medical Society and the Danbury Medical Society and had also been chairman of the board of trustees and president of the Fairfield County Medical Society. He once served as coroner physician to the town of New Fairfield and surgeon to the New York New Haven and Hartford Railroad. Associated with the Danbury Hospital since 1885, Dr Brown had been surgeon since 1902. At one time he had been medical aide to the governor of Connecticut and chairman of the medical section of the state committee of the National Council of Defense. In 1917 he was commissioned a captain in the medical corps of the U S Army becoming in 1918 a major in the medical section of the Provost Marshal General's Office. At the time of his death Dr Brown was chairman of the local committee on medical aid of the committee on disaster preparedness and relief of the American Red Cross.

Long after his official connection ended with the Committee on Scientific Exhibit of the American Medical Association Dr Brown continued an active interest in the affairs of the committee appearing regularly at its meetings. It was during his term as chairman that the committee showed unprecedented development and to him goes credit for the bureau's participation in the expansion of medical education. His enthusiastic attention to the affairs of local and state medical matters evidenced his keen interest in the progress of organized medicine. Dr Brown was a kindly and companionable man and his genial manner his energy and his tact endeared him to many.

Norval Albert Hamilton ☼ Franklin Ohio Miami Medical College Cincinnati 1890 chairman of the county Selective Service Board vice president of the Miami Valley Building and Loan Association a director of the Franklin National Bank past president and charter member of the Franklin Rotary Club formerly secretary of the Warren County Medical Society, for many years a member of the Warren County Board of Elections on the staff of the Middletown (Ohio) Hospital past president of the U S Board of Pension Examining Surgeons aged 73 died March 28 in the Christ Hospital Cincinnati of chronic myocarditis.

Walter Henry Adams, Northampton Mass. University of the City of New York Medical Department 1889 for many years on the staff of the Cooley Dickinson Hospital aged 78 died March 18 in Fresno Calif. of arterio sclerotic heart disease.

Joel Young Alexander ☼ Middleton Tenn. University of Nashville Medical Department 1907 aged 62 died March 18 of heart disease.

Reuben Harry Alpert ☼ New Haven Conn., Yale University School of Medicine, New Haven 1913 member of the American Society of Anesthetists, Inc., anesthetist to the Griffin Hospital, Derby, and the Grace Hospital, aged 53, died, February 5, of staphylococci meningitis.

Henry Pendleton Ball, La Jolla Calif., Kansas City (Mo.) Medical College, 1883, University of the City of New York Medical Department 1884, member of the Missouri State Medical Association, formerly medical examiner for the Kansas City (Mo.) Life Insurance Company aged 83, died March 11 in the Scripps Memorial Hospital of cerebral hemorrhage.

William Pawson Chunn, Baltimore University of Maryland School of Medicine, Baltimore 1880 member of the Medical and Surgical Faculty of Maryland aged 84 died February 19.

Hale Ellicott Cullom, Nashville Tenn., Vanderbilt University School of Medicine Nashville, 1930 served as a captain in the medical corps of the U S Army, director of sight conservation and prevention of blindness for the state of Tennessee son of Dr Marvin M Cullom aged 39 died April 30 in St Thomas Hospital of pneumococci meningitis.

Edward Dodd, Cairo Neb. Keokuk (Iowa) Medical College College of Physicians and Surgeons 1903, member of the board of health of Cairo aged 64 died March 6 of intestinal obstruction.

Francis Louis Donlon, New York Bellevue Hospital Medical College New York 1892 member of the Medical Society of the State of New York formerly chairman of the local school board, for many years consultant to St Joseph's Hospital visiting physician on the staff of St Francis Hospital where he died March 24 of heart disease aged 75.

Arthur I Eccleston, Watertown N Y University of Buffalo School of Medicine 1898, member of the Medical Society of the State of New York served as county coroner and health officer of the town of Carlton aged 69 died March 22 of acute nephritis.

Harry Eckstein, Staten Island N Y University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore 1931 aged 37 died March 21 in the Medical Center New York of carcinoma of the lung with right cerebral metastases.

John Harry Einhouse ☼ Moscow Idaho University of Louisville (Ky.) Medical Department 1921 member of the American Academy of Dermatology and Syphilology for many years one of the university physicians at the University of Idaho served during World War I formerly chief examining physician for the draft board registrar of vital statistics for Latah County aged 49 died March 15 of cerebral hemorrhage.

John Headley Evans ☼ Highland Calif. Kansas City (Mo.) Medical College 1900 also a dentist for thirty four years physician and surgeon for the San Manuel Indian reservation for many years deputy county health officer aged 77 died March 14 of carcinoma of the prostate.

Ernest William Fleming ☼ Los Angeles University of Michigan Department of Medicine and Surgery Ann Arbor 1885 an Affiliate Fellow of the American Medical Association specialist certified by the American Board of Otolaryngology member of the American Laryngological Rhinological and Otolological Society fellow of the American College of Surgeons a founder member of the Los Angeles Ear Nose and Throat Society aged 81 died March 7 of carcinoma of the lungs.

Fred Heywood Freeman Gardiner Maine University of Vermont College of Medicine Burlington 1909 member of the

DAVID CHESTER BROWN, M.D. 1863-1943

Maine Medical Association served overseas during World War I, aged 64, died March 10, in the Gardner General Hospital of coronary thrombosis.

Hiram Brewster Gilmer, Hickory, Miss., University of Tennessee College of Medicine, Memphis, 1924, served in the medical corps of the U. S. Army during World War I, associated with the U. S. Public Health Service for six years, aged 50, was killed March 28, when his automobile plumed off a twelve foot embankment near Meridian.

Arthur Lee Goatcher, Plummerville, Ark., University of Nashville (Tenn.) Medical Department, 1902, member of the Arkansas Medical Society, local surgeon for the Missouri Pacific Railroad, aged 71, died February 25, in St. Anthony's Hospital, Morrilton, of carcinoma of the pincers.

Robert Evans Pearis Gober, Los Gatos, Calif., Bellevue Hospital Medical College, New York, 1881, aged 81, died March 21, of uremia.

Thomas Henry Hack & Proctor, Vt., University of Vermont College of Medicine, Burlington, 1900, health officer of Proctor, on the staff of the Proctor Hospital, aged 72, died March 27, of coronary thrombosis.

Marcus Philip Hambleton, Fontana, Calif., Medical School of Maine, Portland, 1903, member of the California Medical Association, served as a captain in the medical corps of the U. S. Army during World War I, aged 63, died March 16, in a hospital at San Bernardino of injuries received when the automobile in which he was driving was struck by a truck.

Arthur William Harold Olm, Iowa State University of Iowa College of Medicine, Iowa City, 1901, aged 65, died, March 27, in Iowa City of cerebral embolism.

James C. Jenkins, Hartwell, Ga., University of Georgia Medical Department, Augusta, 1897, member of the Medical Association of Georgia, mayor of Hartwell for two terms, aged 68, died February 1, in the Emory University (Ga.) Hospital of diabetes mellitus.

Henry Porter Johnson & Fairmont, Minn., Rush Medical College, Chicago, 1879, an Affiliate Fellow of the American Medical Association, aged 88, died March 31, of arteriosclerosis and bronchopneumonia.

William Sidney Johnson & Carbondale, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1900, for many years deputy coroner of Lackawanna County, on the staff of St. Joseph's Hospital, aged 67, died March 5, of heart disease.

Thomas Frank Kennedy, Woonsocket, R. I., College of Physicians and Surgeons, Baltimore, 1900, member of the Rhode Island Medical Society, aged 68, served on the staffs of St. Joseph's Hospital, Providence, Park Place Hospital, Pawtucket, and the Woonsocket Hospital, where he died, March 10, of pneumococcal meningitis following otitis media.

Fred William Linn & Cleveland, University of Wooster Medical Department, Cleveland, 1900, on the senior staff of the Lutheran Hospital, aged 65, died March 31, of myocardial infarction.

Homer M. Little, East St. Louis, Ill., Marion-Sims College of Medicine, St. Louis, 1900, member of the Illinois State Medical Society, aged 72, served on the staffs of the Christian Welfare Hospital and St. Mary's Hospital, where he died, March 14, of coronary occlusion.

Carleton Mathewson, Fresno, Calif., Cooper Medical College, San Francisco, 1900, member of the California Medical Association, served with the U. S. Public Health Service during World War I, for twenty-five years health officer of Fresno, on the staff of the Burnett Sanitarium, aged 67, died, March 1, in St. Agnes Hospital of heart disease.

Albert Bascom Price, Gordo, Ala., Medical College of Alabama, Mobile, 1898, member of the Medical Association of the State of Alabama, past president of the Pickens County Medical Society, aged 74, died, March 3, of coronary thrombosis.

George Merwin Redman, Chicago, Chicago Medical School, 1921, member of the Illinois State Medical Society, served on the staffs of the Evangelical Hospital, St. George Hospital and the Southtown Hospital, where he died, March 27, of perforated duodenal ulcer.

Paul De Witt Robason & McKinney, Texas, Fort Worth School of Medicine, Medical Department of Texas Christian University, 1917, served overseas during World War I, past president and secretary of the Collin County Medical Society, aged 49, president of the staff of the McKinney City Hospital, where he died, March 13, of acute arthritis, bacteremia, pericarditis, myocarditis and acute nephritis.

Leo Frank Secrist, Alpena, Mich., University of Michigan Homoeopathic Medical School, Ann Arbor, 1911, member of the Michigan State Medical Society, past president of the Alpena County Medical Society, a member and formerly chief of the staff of the Alpena General Hospital, aged 56, was found dead, March 9, of coronary occlusion and bronchopneumonia.

Lawrence Crosby Snow & Salt Lake City, Jefferson Medical College of Philadelphia, 1914, member of the American Academy of Orthopaedic Surgeons, specialist certified by the American Board of Orthopaedic Surgery, Inc., while a resident of Park City served as city and county physician and as director of the State Bank, aged 56, on the staffs of the Holy Cross Hospital, Primary Children's Hospital and the Dr. W. H. Groves Lutter-Day Saints Hospital, where he died, March 25, of hypertension and cardiac asthma.

Charles Henry Upton, Los Angeles, Bennett College of Eclectic Medicine and Surgery, Chicago, 1902, aged 67, died, March 6, of coronary thrombosis.

Frank Forrest Urey & New Castle, Pa., Western Pennsylvania Medical College, Pittsburgh, 1900, also a pharmacist, served during World War I, chief surgeon of the ear, nose and throat department, Jameson Memorial Hospital, aged 70, died, March 8, of carcinoma of the pancreas.

Harry A. Vedder, Marshfield, Wis., Northwestern University Medical School, Chicago, 1905, on the staff of St. Joseph's Hospital, joined the Marshfield Clinic in 1920, surgeon for the Chicago, Northwestern and Omaha Railway Company for many years, aged 63, died, March 12, of myocarditis, chronic endocarditis and cirrhosis of the liver.

Carl von Neupert & Stevens Point, Wis., Louisville (Ky.) Medical College, 1892, past president of the Portage County Medical Society, fellow of the American College of Surgeons, examining physician and surgeon for the Soo Line Railroad for more than forty years, for many years served as county physician, member of the staff and formerly president of St. Michael's Hospital, aged 72, died, March 15, of heart disease.

Solomon Le Roy Walthall, St. Louis, University of West Tennessee College of Medicine and Surgery, Memphis, 1914, aged 56, on the visiting staffs of the Peoples Hospital, Homer, G. Phillips Hospital and St. Mary's Infirmary, where he died, March 14, of cerebral hemorrhage.

Fonso Butler Watkins & Morganton, N. C., Jefferson Medical College of Philadelphia, 1907, fellow of the American College of Physicians, president of the North Carolina Neuropsychiatric Association, in 1938 became superintendent of the State Hospital after having served for twenty-six years as first assistant physician, aged 64, died, March 8, in the Rutherford Hospital, Rutherfordton, of toxic cirrhosis of the liver.

Annie Roberts Young, Waltham, Mass., Tufts College Medical School, Boston, 1911, at one time a member of the school committee of Waltham, aged 79, died, March 16, in Wellesley of myocarditis and arteriosclerosis.

DIED WHILE IN MILITARY SERVICE

Louis Archie Milne & Colonel, M. C., U. S. Army, Brooklyn, Kansas City (Mo.) Medical College, 1904, U. S. Army Medical School, Washington, D. C., 1935, practiced at Lawton, Okla., where he had been a contract surgeon for the Indian Reservation, in 1916 served as a medical officer on the Mexican border, served during World War I, became a captain in the medical corps of the U. S. Army in 1920 and rose through the various ranks to that of colonel, port surgeon of the New York Port of Embarkation, aged 63, died, March 6, in the Fort Hamilton Station Hospital of cerebral embolism.

Howard Hopley Barlow, Salem, Ore., State University of Iowa College of Medicine, Iowa City, 1920, a member of the staffs of the Salem General and Salem Deaconess hospitals, captain medical corps, Army of the United States, aged 47, died, April 8, in the Barnes General Hospital, Vancouver, Wash., of coronary thrombosis.

William Thau, Boston, Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1924, captain in the medical corps of the Army of the United States, assigned to the Station Hospital at the Indiantown Gap Military Reservation in Pennsylvania, where he died, February 14, of a skull fracture received in an automobile accident, aged 45.

"BLACK DERMOGRAPHISM"

To the Editor—With reference to the article "The Phenomenon of 'Black Dermographism'" by Urbach and Pillsbury in THE JOURNAL February 13, any one sufficiently interested in the subject to attempt to analyze the data presented may find them rather confusing. Data of this sort should be accurate and properly presented contribute to an ultimate solution of the phenomenon on theoretical grounds. I should like to suggest in passing, however, that the explanation is to be found in an analytic study of the reactions and deposit on the skin rather than through a study of the materials which may or may not "prepare" the skin for the test.

As to my criticism of the clarity of the article, particular reference is made to the second paragraph on page 487 which is quoted here for reference: "Table 6 shows how differently the various salts of the same metal used in preparation of the skin react, even such closely related compounds as sodium sulfate and sodium sulfite, for example. We would stress that with the exception of sodium sulfite all sulfur compounds react negatively and that therefore the suggestion that black dermographism might be due to a sulfur compound (e. g. silver sulfide) may be promptly dismissed." The reference is obviously to table 7 rather than to table 6 whereas an earlier reference (p. 486) to table 7 is obviously meant for table 6. To repeat, "We would stress that, with the exception of sodium sulfite all sulfur compounds react negatively." This "exception" namely sodium sulfite, is, however, listed in table 5 as one actually giving a negative result. In table 7 on the other hand, this compound, as well as seven other sulfur-containing compounds, is credited with producing positive reaction while only two (aluminum sulfate and sodium sulfate) are given as negative. The positive reactions of the seven compounds just mentioned are confirmed in table 4 while table 5 fails to add any to the list of two negatively reacting substances (with the exception of sodium sulfite).

These data hardly seem to support the authors' ready dismissal of the suggestion that black dermographism might be due to a sulfur compound.

L. F. NEV, Edgewood Arsenal, Md.

[A copy of Mr. Nev's comment, sent to the author of the article, brought this reply.]

To the Editor—Dr. Pillsbury and I fully agree that the ultimate solution of the phenomenon of black dermographism is to be found in the analytic study of the deposits. To this end photospectrometric examinations were presented showing that the black lines consisted of silver or copper depending on the composition of the metal used for the experiment (see figs. 4 and 5). This closely corresponds with the chemical analysis by Hauck and Dietel, cited in the paper.

As regards the role of sulfur in the elicitation of this phenomenon two points are significant. 1. Many substances entirely free of sulfur such as titanium dioxide and calcium carbonate, call forth positive reactions. 2. While certain sulfur compounds react positively, others including aluminum sulfate and sodium sulfite as well as precipitated, sublimed and washed sulfur react negatively. It seems proper to conclude therefore, that black dermographism is definitely not based on a chemical reaction between sulfur or sulfur compounds and the metals used for stroking.

It is a regrettable error that sodium sulfite was included as a negative reacting substance in table 5.

ERICH URBACH, M.D., Philadelphia

NUTRITION PLANNING

To the Editor—The coming International Food Conference at Hot Springs is expected among other things to see that sufficient and proper food will be available during the present war and the postwar period. The conference will also make far reaching recommendations and will probably advise the various countries as to the quantity and type of foodstuffs they are expected to produce. The predominantly grain producing countries will have to produce according to some plan in order to avoid overproduction of certain foodstuffs. Cattle and sheep raising countries will likewise produce according to the protein requirements of the populations concerned. In making these recommendations the conference will undoubtedly be guided by fundamental human nutritional needs as determined by medical science.

In general, the mineral requirements of the human being are well established as also the requirements of the known vitamins. The protein, fat and carbohydrate requirements should be definitely established. This will be a difficult problem and will lead to controversy because there will be disagreement as to the requirements of protein, fat and carbohydrate.

In recent years several common diseases and disorders have been successfully treated with diets high in protein and low in carbohydrate rich foods. I refer to such diseases and disorders as arthritis, peptic ulcer, colitis, angina pectoris, tuberculosis, dyspepsia, flatulence, abdominal pain, certain neurotic states and ordinary headaches. The results have been so striking as to force the conclusion that the fundamental cause of these pathologic states is due, in the main, to the consumption of carbohydrate rich foods. Having had a considerable experience in treating patients with these diseases and disorders during the past five years I have been forced to conclude that the American diet is harmful because it allows a great amount of carbohydrate rich foods. It has also become apparent that, even though the diet may contain a sufficient amount of protein, fat, minerals and vitamins, the presence of carbohydrate rich foods will exert their harmful effects just the same. This was clearly demonstrated in the treatment of advanced pulmonary tuberculosis. Patients who were going downhill on a scientifically prepared hospital diet containing carbohydrate rich foods and required amounts of protein, fat, minerals and vitamins responded immediately to a diet which eliminated all carbohydrate rich foods. From such observations on patients with tuberculosis one may justifiably conclude that the consumption of carbohydrate rich foods is perhaps, the most important factor in susceptibility to tuberculosis. Faber of Denmark in a study of tuberculosis mortality in Europe during World War I, found that the increase in tuberculosis mortality in all countries investigated coincided with an increased consumption of flour and potatoes and a decreased consumption of meat, fish and dairy products. The increase in mortality occurred in spite of an adequate caloric intake. When conditions permitted an increased consumption of protein and fat and a decreased consumption of carbohydrate rich foods the tuberculosis mortality fell.

That good nutrition is essential to the maintenance of health is recognized by all. Good nutrition is a vague term; it means not only sufficient calories and food of adequate quality and quantity but also a greater amount of protein and fat and far less carbohydrate rich foods than present day standards permit. I would recommend that the consumption of carbohydrate rich foods by human beings be ultimately discontinued. Carbohydrate should be ingested only in the form of 5 and 10 per cent vegetables and fruits.

MEDICOLEGAL ABSTRACTS

Malpractice Performance of Unnecessary Operation by Osteopath—The plaintiff, a man aged 22, consulted the defendant, an osteopath, relative to dark circles under his eyes and was advised that an operation, which the osteopath agreed to perform for \$100 cash in advance, would correct the condition. The patient returned the next day, paid the osteopath \$100 cash and signed a paper presented to him by the osteopath, reading as follows:

To Whom It Concerns:

This will certify that I have requested [naming the osteopath] to perform plastic surgery upon my person & assume full responsibility for any untoward happening, infection, scarring, occurrence or recurrence of a deformity that may develop.

The patient objected to signing such a paper, stating that if there was any danger at all in the operation he (the patient) did not want to go through with it, but the osteopath assured him that the osteopath's insurance carrier required the signing of such a paper and that, in the words of the patient, "he could do me a neat and satisfactory job, the kind I really would like to have and he could do it." The following day the osteopath operated on the patient, removing "the pigmented skin under the eyes in an effort to eliminate the dark circles." The operation, according to the Supreme Court of Missouri, division No. 1, admittedly "was unnecessary and not successful." Twenty-eight days later the osteopath for another \$50 cash in hand paid, performed a second operation "by removing skin at the side of the eye in an attempt to remedy a drooping of the lower lid from the eyes." The patient subsequently sued the osteopath for malpractice and recovered a judgment for \$12,000. The osteopath appealed to the Supreme Court of Missouri, division No. 1.

The trial court had instructed the jury that if it found that the dark areas or circles under the patient's eyes were not caused by any ailment or disease and that an operation for the removal thereof would be likely to result in injury to the patient, and that the osteopath knew or by the exercise of ordinary care and skill could and should have known that the removal of such dark areas by an operation was so obviously

unnecessary that an ordinary careful and prudent surgeon would not have performed it, and that such operation was likely to result in injury to the patient and notwithstanding such knowledge, if any, advised such operation and performed it, and that as a direct result of the operation by the defendant the plaintiff was injured, then the verdict of the jury should be for the patient and against the osteopath. The osteopath contended that the instruction was erroneous because there was no evidence tending to show that the operation was likely in all probability to result in injury. The fact, said the Supreme Court, that the osteopath asked his patient to sign the release tended to show that the osteopath had doubts about the result of the operation and thought it likely to result in injury. Furthermore there was evidence tending to show that the skin under the eyes of "youngsters" from 20 to 25 years of age fits tightly to other tissues, that the "natural and probable consequences" of the operation would be a contracted lid and that the skin under the patient's eyes had been normal. All of this, concluded the court, was substantial evidence tending to show that the operation would likely result in injury.

The osteopath further objected to the instruction, arguing that the jury might have understood the word "injury" used in the instruction to mean the mere cutting of the skin. We do not think that there is any merit to this argument, answered the court. As the word "injury" was used in the instruction the jury would understand the word to mean the ultimate result of the operation. The osteopath also contended that the use of the word "likely" in the instruction broadened the issues. The instruction, said the court, requires a finding that the operation would likely result in injury, whereas the petition filed by the patient alleged that the osteopath knew or, by the exercise of ordinary care, should have known that the operation would result in injury. If the osteopath knew that the operation would result in injury, continued the court, it necessarily follows that he knew it would likely result in injury. In other words, an allegation that the osteopath knew that the operation would result in injury includes an allegation that he knew it would likely result in injury. If so, the instruction does not broaden the issues made by the pleadings. On the contrary, it narrows such issues. Furthermore, the evidence shows that the case was tried on the theory that the operation would likely in all probability result in injury and not on the theory that the defendant had actual knowledge that injury would result from the operation. Thus it appears that the osteopath is not in a position to complain of the word "likely" in the instruction.

The osteopath next contended that the patient tried the case on the theory that the pigmentation of the skin was due to disease and for that reason it was error to require the jury to find that that condition was not due to disease. The osteopath relied on the testimony of a physician called by the patient to sustain his contention. That physician testified that the dark circles under the eyes of the patient were not the result of disease, that the operation should not have been performed, that the proper treatment was medical in that the boy's life should have been regulated and attention given to nutrition. It thus appears, answered the Supreme Court, that this physician's testimony does not sustain the osteopath's contention. Furthermore, the record shows that the pigmentation of the skin under the eyes was a mere discoloration which was not the result of disease. The only evidence even remotely bearing on this contention was the testimony of the osteopath to the effect that the condition was a local disorder.

The osteopath also contended that the instruction erroneously directed a verdict for the patient without a finding that it was negligence on the part of the osteopath to perform the operation. But, answered the court, as was said in *Jones v. Central States Oil Co.*, 164 S. W. (2d) 914, 919:

If an instruction requires the jury to find facts which, if true, could only mean that the defendant was guilty of negligence per se or as a matter of law, then the instruction is good even if it does not require the jury to find that such facts constitute negligence, because "the law draws the conclusion in such cases."

If the osteopath knew that the operation was unnecessary and likely to result in injury, he would be guilty of negligence as a matter of law if he advised the operation and performed it. On this, reasonable minds cannot differ. Furthermore, if the osteopath was without actual knowledge as to the result of

This later behaves as a "unit" 3 Resolution or absorption begins by (a) generalized and uniform progressive (three to five days) loss of density throughout the "unit," (b) the appearance of "wire grass" infiltration or 'pseudofibrosis' and (c) eventual progressive complete clearing of single units in five to fourteen days 4 There was occasional development of multiple "units" with (a) subsequent definite dates of onset and individual chronology, (b) rare involvement of all visible parts of a lung and (c) usually no one unit disturbed the approximate prearranged chronology of any restarted unit 5 Its occurrence in children is typical

Duodenal Ulcer Syndrome Caused by Ancylostomiasis—In localities in which ancylostomiasis is common dyspepsia associated with severe anemia suggests the diagnosis of hookworm disease, but in countries in which this disease is infrequent ancylostomiasis as a cause of painful dyspepsia is often ignored and not considered in the differential diagnosis. When hookworm disease causes symptoms suggestive of duodenal ulcer a definite diagnosis can be made only by finding the ova of *Ancylostoma* in the stools and by roentgen study of the gastrointestinal tract. Yenikoni-Hian and Shehadi have had patients whose clinical history was suggestive of chronic duodenal ulcer but whose stools contained the ova of *Ancylostoma* duodenale and who were relieved completely of their digestive symptoms soon after the infection was cleared up. The fact that some of these patients gave no history of recent hematemesis or malaria and had severe microcytic anemia prompted the authors to investigate the gastric acidity and to make roentgen studies of the gastrointestinal tract of patients with ancylostomiasis. The estimation of free gastric acidity showed a rise to a higher level than that obtained in duodenal ulcer. In spite of the varying degrees of anemia, this high gastric acidity was maintained. Roentgen studies of these cases show evidence of swelling of the duodenal mucosa, inconstant deformity of the duodenal bulb (duodenitis without an ulcer niche), hyperperistalsis of the stomach and the duodenum and commonly reverse peristalsis of the duodenum without obstruction. The administration of a vermifuge resulted in the elimination of epigastric pain within twenty-four hours and the restoration of the duodenal wall to normal within eleven to twenty-four days.

Radiation Therapy of Postoperative Parotitis—Postoperative parotitis is a serious complication. In contrast to simple parotitis or mumps it has a short incubation period; it tends to suppurate and its mortality rate is high. Many forms of therapy have been advocated. Between May 1940 and August

1941 Patterson encountered 5 instances of postoperative parotitis in his service; he treated them by radiation therapy with recovery in all. Aside from irradiation, which was begun early, only local treatment was employed; this probably explains why suppuration was imminent only in some glands. As a prophylactic measure no elective surgery should be done when foci of infection are present in the nose, mouth or throat. Debilitated and dehydrated patients should receive proper preoperative treatment.

Frostbite in Shipwrecked Mariners—The 71 cases of frostbite incurred in the battle of the Atlantic were treated by Brownrigg according to whether the frostbite was principally characterized by erythema, 55 cases, a dusky red to black color of the affected part with restricted movement, 7 cases, or the foregoing changes with toxicity and fever, 9 cases. In first degree frostbite rest, elevation and strict attention to asepsis resulted in a rapid complete or nearly complete amelioration of the condition. In a few considerable disability persisted because of persisting thickening and stiffness of the toes, feet and, in 1 case, of the hands. This was due to the formation of fibrous tissue. Anything (refrigeration, vasoconstrictor drugs) that will minimize this may be of considerable value. In the treatment of second degree frostbite the ideal treatment is to allow spontaneous separation of the areas of dry gangrene, to trim necrotic bone and to permit healing by granulation. This preserves maximal function. In third degree frostbite amputation must be performed sufficiently high to remove all areas of gangrene. The prevention of frostbite in shipwrecked mariners is difficult but clothing which would prevent heat loss and be waterproof for at least the lower extremities would be a great advancement. Sott sealskin boots might be of considerable value.

Incipient Thromboangitis Obliterans in Young Draftees—Physicians examining young men of the draft age who describe symptoms of peripheral vascular disease, Jahsman and Durham caution should remember that thromboangitis obliterans can and does occur in young men and make every effort to rule this disease in or out as it may constitute a definite compensation risk. When draft boards refer men for special investigation because of a suspicion of peripheral vascular disease the routine examination should include capillaroscopy and the response of the cutaneous temperature to heat and cold. During the last seven months the authors have encountered 7 such cases. 3 were in draftees referred for study and 1 in a youth of 19 in the Michigan National Guard. One foot and leg were invariably more involved than the other. There may be symptoms in a single digit. At least some involvement of the larger arteries was demonstrated in the slight to moderate organic occlusion revealed by the dermaterm study in each of the 4 young men; none showed complete occlusion. Once the disease is diagnosed in young men they should be kept reasonably free from symptoms and subsequent complications prevented by teaching them more moderate habits of living and meticulous care of the feet.

Sulfonamide Therapy of Bacterial Endocarditis—During 1935 to 1941 inclusive 67 patients with bacterial endocarditis were admitted to the Charity Hospital. 42 of them were treated with one or more of the sulfonamides. *Streptococcus viridans*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Chronic Gastritis—In a relatively large number of stomachs resected because of ulcer or carcinoma but also presenting features of chronic gastritis, Hebbel tried to verify the character and distribution of the reported mucosal changes in relation to ulcer and carcinoma. The stomachs from patients who died without manifest gastric disease were also examined. The changes exhibited by this group were chiefly those of a pyrogastritis leading to atrophy. The process bore no demonstrable relationship to any factor other than age. Atrophic gastritis was exhibited by 30 per cent of the stomachs of 108 patients more than 50. This form of gastritis is unimportant in patients less than 50 whose stomachs are resected. Among the 106 stomachs resected for ulcer there was an antral gastritis in the 98 in which the antrum was examined. Changes in the body mucosa were rare in the stomachs with duodenal ulcer and common in those with gastric ulcer. The evidence substantiates the contention that an antral gastritis (and duodenitis) precedes, and is the anatomic basis for, the development of chronic ulcer. The gastric changes in 52 stomachs resected for carcinoma were variable. Although in many a diffuse atrophic gastritis undoubtedly antedated the tumors, the condition did not obtain in all. In a few, although there were severe changes near the tumor, the more distant portions of the excised segments were less, or not at all, affected. This suggested that the mucosal changes were secondary to the tumor, although the possibility of a coincidental association could not be excluded. The series did not indicate that carcinomas frequently arise in stomachs in which diffuse atrophic gastritis is already present.

Virus Pneumonia—In a group of 221 cases of nonlobar (non-pneumococcal) pneumonia, the clinical and laboratory observations of which correlate well with previously described groups of febrile episodes apparently due at least in part to infection with a filtrable virus, Seeds and Mazer were able to demonstrate certain pulmonary roentgen characteristics over and above "distribution unusual to lobar pneumonia" and inconstancy within its own group. They have found the following roentgen characteristics: 1. There was an infiltrative process which at the onset was (a) first progressively peribronchial and (b) customarily clearly definable as to limits in spite of its disregard for segmental or lobar structural limits, usually involving more than one segment and frequently parts of more than one lobe. 2. This was quickly accompanied by a "cottonwool" appearance of multiple areas of partial or semi consolidation, which was scattered through the area of infiltration and usually also distributed in a radial progression, frequently coalesced subsequently (six to twenty-four hours) and occasionally filled eventually (twenty-four to forty-eight hours) approximately a whole lobe to simulate lobar pneumonia but with a striated infiltrative type of background rather than a pure homogeneity, and a fixed distribution for any one area was established in two to three days.

This later behaves as a 'unit' 3 Resolution or absorption begins by (a) generalized and uniform progressive (three to five days) loss of density throughout the 'unit,' (b) the appearance of "wire grass" infiltration or 'pseudofibrosis' and (c) eventual progressive complete clearing of single units in five to fourteen days 4 There was occasional development of multiple 'units' with (a) subsequent definite dates of onset and individual chronology, (b) rare involvement of all visible parts of a lung and (c) usually no one unit disturbed the approximate prearranged chronology of any restarted unit 5 Its occurrence in children is typical

Duodenal Ulcer Syndrome Caused by Ancylostomiasis—In localities in which ancylostomiasis is common, dyspepsia associated with severe anemia suggests the diagnosis of hookworm disease, but in countries in which this disease is infrequent ancylostomiasis as a cause of painful dyspepsia is often ignored and not considered in the differential diagnosis. When hookworm disease causes symptoms suggestive of duodenal ulcer a definite diagnosis can be made only by finding the ova of *Ancylostoma* in the stools and by roentgen study of the gastrointestinal tract. Yenikomshian and Sheliadi have had patients whose clinical history was suggestive of chronic duodenal ulcer but whose stools contained the ova of *Ancylostoma duodenale* and who were relieved completely of their digestive symptoms soon after the infection was cleared up. The fact that some of these patients gave no history of recent hematemesis or malaria and had severe microcytic anemia prompted the authors to investigate the gastric acidity and to make roentgen studies of the gastrointestinal tract of patients with ancylostomiasis. The estimation of free gastric acidity showed a rise to a higher level than that obtained in duodenal ulcer. In spite of the varying degrees of anemia, this high gastric acidity was maintained. Roentgen studies of these cases show evidence of swelling of the duodenal mucosa, inconstant deformity of the duodenal bulb (duodenitis without an ulcer niche), hyperperistalsis of the stomach and the duodenum and commonly reverse peristalsis of the duodenum without obstruction. The administration of a vermifuge resulted in the elimination of epigastric pain within twenty-four hours and the restoration of the duodenal wall to normal within eleven to twenty-four days.

Radiation Therapy of Postoperative Parotitis—Postoperative parotitis is a serious complication. In contrast to simple parotitis or mumps it has a short incubation period, it tends to suppurate and its mortality rate is high. Many forms of therapy have been advocated. Between May 1940 and August

1941 Patterson encountered 5 instances of postoperative parotitis in his service; he treated them by radiation therapy with recovery in all. Aside from irradiation, which was begun early, only local treatment was employed; this probably explains why suppuration was imminent only in some glands. As a prophylactic measure no elective surgery should be done when toxic infection are present in the nose, mouth or throat. Debilitated and dehydrated patients should receive proper preoperative treatment.

Frostbite in Shipwrecked Mariners—The 71 cases of frostbite incurred in the battle of the Atlantic were treated by Brownrigg according to whether the frostbite was principally characterized by erythema, 55 cases, a dusky red to black color of the affected part with restricted movement, 7 cases, or the foregoing changes with toxicity and fever, 9 cases. In first degree frostbite rest, elevation and strict attention to asepsis resulted in a rapid complete or nearly complete amelioration of the condition. In a few considerable disability persisted because of persisting thickening and stiffness of the toes, feet and, in 1 case, of the hands. This was due to the formation of fibrous tissue. Anything (refrigeration vasoconstrictor drugs) that will minimize this may be of considerable value. In the treatment of second degree frostbite the ideal treatment is to allow spontaneous separation of the areas of dry gangrene, to trim necrotic bone and to permit healing by granulation. This preserves maximal function. In third degree frostbite amputation must be performed sufficiently high to remove all areas of gangrene. The prevention of frostbite in shipwrecked mariners is difficult, but clothing which would prevent heat loss and be waterproof or at least the lower extremities would be a great advancement. Sott sealskin boots might be of considerable value.

Incipient Thromboangitis Obliterans in Young Draftees—Physicians examining young men of the draft age who describe symptoms of peripheral vascular disease, Jahsman and Durham caution, should remember that thromboangitis obliterans can and does occur in young men and make every effort to rule this disease in or out, as it may constitute a definite compensation risk. When draft boards refer men for special investigation because of a suspicion of peripheral vascular disease, the routine examination should include capillaroscopy and the response of the cutaneous temperature to heat and cold. During the last seven months the authors have encountered 7 such cases, 3 were in draftees referred for study and 1 in a youth of 19 in the Michigan National Guard. One foot and leg were invariably more involved than the other. There may be symptoms in a single digit. At least some involvement of the larger arteries was demonstrated in the slight to moderate organic occlusion revealed by the dermatograph study in each of the 4 young men; none showed complete occlusion. Once the disease is diagnosed in young men they should be kept reasonably free from symptoms and subsequent complications prevented by teaching them more moderate habits of living and meticulous care of the feet.

Sulfonamide Therapy of Bacterial Endocarditis—During 1938 to 1941 inclusive 67 patients with bacterial endocarditis were admitted to the Charity Hospital, 42 of them were treated with one or more of the sulfonamides. *Streptococcus viridans*

was present in the blood cultures of 21 of the 42 patients. All of the 67 patients died. In some there were temporary remissions in the curve of the temperature, but the course of the disease was apparently unaffected by the treatment. Galbreath and Hull observed characteristic lesions of acute or subacute vegetative endocarditis in the 30 patients on whom necropsy was performed. There was no evidence of healing of the lesions. Evidence of embolism was present in 28. The kidneys and spleen were the most frequent sites of infarction, but infarcts of the brain, lungs, heart, liver and thyroid also were encountered.

Treatment of Syphilis with Phenarsine Hydrochloride—During the last two months Long has given 2,033 injections of phenarsine hydrochloride to 96 syphilitic patients. This new trivalent arsenical preparation is 3 imino-4 hydroxyphenyldichloroarsine hydrochloride. *Treponema pallidum* rapidly disappeared from infectious lesions, all lesions of early and late syphilis healed rapidly and completely, clinical or infectious relapse did not occur, the serologic reversal was satisfactory and the incidence of abnormal spinal fluids among patients with early syphilis was low. Patients with late syphilis tolerated the drug, their symptomatic improvement was good and the results were entirely satisfactory. Toxic reactions were few, chiefly mild gastrointestinal disturbances. The results suggest that phenarsine hydrochloride is a potent antisyphilitic drug of low toxicity, and the treatment of larger groups of patients appears justified.

Phenarsine Hydrochloride for Syphilis—Guy, Goldmann and Cannon have been studying the effect of phenarsine hydrochloride on established syphilis. From their preliminary study they feel that the information so far derived suggests that phenarsine hydrochloride may prove more stable than and that it compares favorably with (as to administration and toxicity reports so far) other drugs which are now available and which depend for their efficacy on arsenoxide.

Introduction to pH of Throat—Fabricant determined the normal, physiologic range in the pH of the clinically normal throats of 51 men and women. By taking minute to minute readings and utilizing a glass electrode and a Coleman elec-

trode, he found the normal physiologic pH values to range from 4.9 to 8. For 54.8 per cent of the subjects the values were within the acid range, for 7.8 per cent within the alkaline range and for 37.4 per cent they fluctuated within a slightly acid, slightly alkaline range. Therefore the throat normally can be either acid or slightly alkaline. The claims advanced by the manufacturers of some local throat medicaments that their particular variety "neutralizes excess acidity in the mouth and throat" and that therefore their product is superior can be challenged when it becomes clear that normally the pH of the throat is usually within an acid range. Before final suggestions can be made for an appropriate physiologic pH for a local throat medication, the range of pH values for the diseased throats of persons and the effect of the local medication on the pH of the throat in health and in disease must be determined.

Sulfonamides and Nasal Mucosa—Gundrum instilled three times a day ten drops of one of the following solutions into each nostril of rabbits: a 4.7 per cent solution of sodium sulfathiazole, sulfadiazine or butanoylsulfanilamide or a solution containing neosynephren hydrochloride for various periods of time. Immediately after the last instillation the animals were killed by intravenous injection of air and their noses were embedded in petrolatum and then examined. There seemed to be considerable discomfort (evidenced by restlessness and audible sounds of distress) after prolonged intranasal application of the sulfonamide compounds. After six days of treatment the mucocutaneous junction of the external nares in all animals treated with butanoylsulfanilamide showed redness, some excoriation and other evidence of severe irritation. At necropsy all animals treated with sulfonamide compounds showed inflammation throughout the nose. This appeared more pronounced in animals treated with sodium sulfathiazole and butanoylsulfanilamide. The posterior portion of the nose was filled with a grayish exudate. The mucous membranes were decidedly thickened. No evidence of injury to bone or cartilage was observed, although there were some areas at which the perichondrium was swollen and desquamated. The sinuses were filled with abundant exudate, consisting of degenerated epithelial cells, round cells, a few giant cells and masses of debris. The destruction seemed as great in the animals treated for ten days as in those treated for thirty days. No apparent discomfort was caused by the instillation of neosynephren hydrochloride and at necropsy the nasal mucosa remained unchanged. Sections of the lungs revealed no significant changes in the mucosa of the bronchial tree of animals treated with sulfonamide compounds or with neosynephren hydrochloride.

Chemotherapy of Experimental Streptococcal Pericarditis—Lebowich compared the therapeutic efficacy of sulfanilamide and an acetylated derivative of 4,4'-diaminodiphenylsulfone hydrochloride in experimental beta hemolytic streptococcus pericarditis in rabbits. With the object of reducing the acute toxicity of the latter ascorbic acid, nicotinic acid, dextrose, cysteine, ammoniacetic acid and acetic acid and its *in vivo* precursors (lactic and pyruvic acids) was tried. After many trials 1 molar acetic acid was selected as the most satisfactory agent. The administration of acetic acid with the sulfone compound definitely lessened the severe acute and chronic toxic effects of the sulfone compound in rabbits. At the same time it did not

tion for the absence of convulsions or coma in some dogs. In dogs anesthetized with pentobarbital sodium the blood sugar level dropped more rapidly after the administration of insulin than in the unanesthetized animal. The decrease in lymph sugar lagged considerably behind that in blood sugar during the first hour following insulin in the anesthetized dog, but the lymph sugar reached equilibrium with the blood in this respect more rapidly than did the peritoneal fluid. The relation of coma and convulsions to the dextrose content of the peritoneal fluid suggests that the latter may be representative of the normal concentration of dextrose in interstitial fluid.

Angina-like Pain in Male Climacterium—Without making any attempt to draw conclusions McGavack records his observations on 8 men in the climacterium with angina-like cardiac symptoms that were relieved with testosterone therapy after other measures had failed. This response may be used as a simple therapeutic test to differentiate complaints of this nature from those of other causation. The clinical features by which the cardiac syndrome of the male climacterium may be recognized are dull, constant oppression over and to the left of the sternum, a sense of uneasiness and insecurity throughout the chest, attacks of angina-like pain and breathlessness not necessarily related to effort and not relieved by glyceryl trinitrate, long sighing respirations, paresthesias of various parts of the body, palpitation without any change in heart rate, depression of the ST segment in all three limb leads, associated climacterium symptoms and the relief of these symptoms within twenty-four to forty-eight hours following the parenteral administration of a testosterone preparation. In using testosterone in this specific type of cardiac complaint which it is capable of relieving, distinction must be made between cardiac neurosis of the climacterium and an organic lesion.

Oral Effectiveness of Estrone Sulfate in Women—Estrone (theelin) sulfate was used by Freed, Eisin and Greenhill in the treatment of women with moderate to severe menopausal symptoms. The doses that were tried were 125, 0.8 and 0.4 mg. three times a day in tablet form. The patients usually received the highest dose at the beginning of treatment, then after two weeks of such therapy the relief of symptoms was evaluated and the next lower dose level was given, and again after two or three weeks the symptoms were evaluated and the lowest dose was given. Most women obtained satisfactory relief from their symptoms with the smallest dose, the larger doses did not appear to increase significantly the relative number of patients who obtained definite relief, but more patients obtained complete relief. However, the smallest dose may be considered adequate for therapeutic purposes for the average patient. Only 1 of the 45 patients on 0.4 Gm. of estrone sulfate three times a day complained of nausea, with the middle dose given to 47 nausea developed in 2 and 2 complained of dizziness, and 5 of the 60 patients on the large dose had nausea and 4 complained of dizziness.

Atypical Pneumonia and Psittacosis—According to Smadel, 10 of the 45 sporadic cases of atypical pneumonia encountered among large eastern urban populations were caused by infection with strains of the virus of psittacosis. Five additional cases in the series may have been psittacosis but the diagnosis was indefinite because a significant rise in antibody titer was not demonstrated in the convalescent serum. In no instance was the virus of lymphocytic choriomeningitis associated with the illness, and in only 2 instances was influenza virus even suspected as a possible etiologic agent. It is important to establish an etiologic diagnosis in cases of atypical pneumonia, and laboratory data are necessary for such a diagnosis. Strains of virus of the psittacosis group which were isolated from 2 patients and from 1 of the patient's pigeons are being studied. Strains isolated from these sources have many properties in common with the strains of psittacosis virus isolated from psittacine birds and from pigeons and with the virus of meningopneumonitis. The authors have been impressed by the high incidence of psittacosis in the 45 patients selected at random and by the frequency with which some sort of association can be demonstrated between the patients and nonpsittacine birds infected with one of the psittacosis group of viruses.

Prophylactic Use of Sulfanilamide in Rheumatic Children—During the winters of 1940-1941 and 1941-1942 Kuttner and Meyersbach divided the 108 rheumatic children at Irvington House into two closely matched groups. Beginning in October 1940 and continuing until the following June, half of the children were given small daily doses of sulfanilamide. The other 54 children served as controls. During the second winter 54 children were given sulfanilamide and 50 served as controls. Only children who showed neither clinical nor laboratory signs of rheumatic activity received this drug. During the first winter 78 per cent of the 108 patients possibly could have had heart disease and 22 per cent had definite cardiac lesions, and during the second winter the percentage with organic heart disease increased to 49 per cent. Streptococcal infections of the upper part of the respiratory tract and rheumatic relapses were prevented by the sulfanilamide. Sufficiently severe toxic manifestations, necessitating the withdrawal of the drug, occurred in

15 per cent of the patients. The other children tolerated the drug well. The effectiveness of sulfanilamide in preventing rheumatic recurrences indicates that infection with group A hemolytic streptococci is an important factor in the causation of rheumatic fever.

Community Study of Carriers in Epidemic Poliomyelitis—Wanner and Casey tested postepidemiologically the stools of 176 or 181 persons living in a section of a small town of 1,670 population to determine the carrier rate for the virus of poliomyelitis in the adult and juvenile population. Most of the town's cases of the disease had occurred in the section where the 181 persons lived. The virus of poliomyelitis was detected in the stools of 3 children between 2 and 6 years of age and in none of the stools from adults. Though evidence of poliomyelitis was widespread in the population, only individuals who were ill at the end of the epidemic had positive stools, indicating that the ease of detection of the virus in the population at risk diminishes with the decline of the epidemic.

Asphyxiated Bacteria as Tuberculosis Vaccine—Potter states that avian tubercle bacilli when completely deprived of virulence by asphyxiation, without the use of coagulating heat retain constituents which are able to confer decided though as yet incomplete protection in the rabbit against infection with virulent avian tubercle bacilli.

Beta Hemolytic Streptococci on Floors of Public Rooms—Walter and Hucker studied the one hundred and thirteen sweepings collected in thirty seven different rooms from six schools a boys dormitory a theater and a hotel. They found beta hemolytic streptococci in the sweepings from twenty-two of the rooms investigated. From February until May hemolytic streptococci could be readily obtained from certain

floors, but with warm weather this was impossible. Physiologic and serologic tests performed on seventeen representative cultures caused the organisms to seven to be classified in Lancefield's group A, two in group B, one in group C and seven possibly in group G.

Chemotherapy of Bacillary Dysentery—Lyon used sulfaguanidine in the treatment of alternate patients with acute bacillary dysentery in an area with what was probably the highest incidence of the disease since 1926. With few exceptions the initial dose was 0.1 Gm per kilogram of body weight, while the maintenance dose was 0.05 Gm per kilogram of body weight administered orally every four hours until the stools were less than five in twenty-four hours and then 0.05 Gm every eight hours for forty-eight to seventy-two hours. An adequate urinary output should be maintained and any untoward effects detected and treated. Sulfaguanidine proved to be an effective therapeutic agent when used in the manner described and if treatment was begun during the first five days of illness recovery usually occurred in two to five days. Usually five days of chemotherapy was all that was required. There were no toxic effects. When chemotherapy was not begun within five days of the onset of fever or diarrhea, results were frequently amazingly good but failures were more frequent.

Toxicity of Tannic Acid—In investigating the toxicity of tannic acid in animals under conditions similar to its clinical use, Robinson and Griessle found that it is definitely toxic for mice and rats when given intravenously or subcutaneously. When applied to deep subcutaneous tissues following surgical removal of the skin, tannic acid was lethal for mice but not for rats or rabbits. Tannic acid or possibly its degradation products could be detected in the urine of all these animals. Hepatic damage was produced in rabbits when tannic acid was administered subcutaneously but not when it was applied to denuded surfaces. Therefore hepatic damage appears to depend on the quantity of tannic acid absorbed. When injected intraperitoneally, tannic acid decidedly depressed the water diuresis of rats. This depression was not produced by large doses of the drug subcutaneously or locally to denuded surfaces.

Toxicity and Efficacy of Penicillin—Robinson tested the toxicity and efficacy of penicillin in certain bacterial virus and protozoan infections in mice. Crude penicillin was toxic for mice when given intravenously in single doses of 0.5, 1, 1.5 and 2 Gm per kilogram of weight. More highly purified preparations appeared to be less toxic. Penicillin given subcutaneously was well tolerated for five daily doses of 1.6 Gm per kilogram of weight. Under the same conditions 3.2 Gm was lethal to some mice. The toxic dose of crude penicillin appears to be about sixty-four times the effective therapeutic dose. On the basis of weight, penicillin appeared more effective than sulfanilamide and its derivatives in streptococcal, pneumococcal and staphylococcal infection in mice. Penicillin had no apparent effect in experimental infection caused by *Mycobacterium tuberculosis*, *Trypanosoma equiperdum* or the influenza virus PR8.

Neurologic Accidents Following Serum Administration—While neurologic accidents following vaccine and serum administered for prophylactic and therapeutic purposes are comparatively rare, the constantly widening field of their use has emphasized their possible role in neurologic disorders of obscure etiology. Carmichael points out that the urticarial rash, articular pains, headache and vomiting with a rise in temperature following administration of serum to the sensitized patient may

be followed immediately or remotely by evidences of neurologic involvement which may be prolonged and seriously disabling. Between 1922 and 1928 the frequent occurrence of these neurologic sequelae, particularly in England and the Netherlands, prompted the appointment of a commission to study the problem. Up to that time 159 cases were studied in England and some 80 odd in the Netherlands. Since this study a large number of cases have been reported in European literature and not a few in this country. The report submitted by the English commission was not conclusive, although it generally was conceded that the specific nature of the antigen was not the factor responsible for the accident but rather a protein sensitivity on the part of the patient. The commission's conclusions are difficult to disprove and are supported by the newer theories relating to the virus infections. The greatest incidence of accidents involving the nervous system followed the prophylactic use of vaccines and serums. Recent discussion as to the exact nature of these sequelae has brought forward various hypotheses. The two that have the most proponents are (1) anaphylactic reaction and (2) the theory that the injection of the protein activates a latent virus always present in the body but which under normal conditions is dormant and innocuous but is pathologic or noxious only in response to some excitant which causes a biochemical change in certain tissue cells vulnerable to attack.

Dissolution of Urinary Calculi—Suby and Albright found that citrate solutions, rendered less irritable by the addition of magnesium, are practical for the dissolution of urinary calculi composed of calcium phosphate, calcium carbonate or magnesium ammonium phosphate. They report 6 cases in which the use of such a solution dissolved the stones partially or completely. In 2 cases the solution was introduced through ureteral catheters and in 4 through nephrostomy tubes. The attempted dissolution of a large stone in 1 patient was not successful because a thin coating of unidentified material, possibly old blood clot, prevented the solution from coming in contact with the stone. Ideally the hydrodynamics should be such that the pressure in the kidney is great enough to get the solution around the stone, but sufficiently intermittent so that constant back pressure does not cause a pyelonephritis. An air pyelogram will indicate whether a stone is in contact with the kidney pelvis and the course of the stone's dissolution. Before attempting to dissolve a stone it is necessary to determine by a roentgenogram whether one is dealing with a phosphatic stone.

- Emblems of Medicine. J. A. Durand, Baton Rouge, La—p. 387

Pelvic Thrombophlebitis—The records of the Charity Hospital for the last five years reveal 41 cases of pelvic thrombophlebitis which was confirmed at operation or proved at necropsy. All but 7 of these patients died. The 41 patients in no way represent the true incidence of the disease, as Nelson

Jones and Collins have no way of determining how many patients recover spontaneously or in how many under conservative management the diagnosis is never established. Still more important, they have no way of determining how many patients die or the condition unless a necropsy is performed in every instance. Delivery, abortion, operation and irradiation were the most frequent precursors. No age group was exempt except, perhaps, childhood. Repeated aerobic and anaerobic blood cultures are necessary to establish the etiology. *Staphylococcus aureus* and nonhemolytic streptococci are frequent offenders. The uterine veins, iliac veins and inferior vena cava were frequently involved. Pulmonary infarction was extremely common, for the diagnosis of which roentgen study should be employed. Ligation of the inferior vena cava appears to lower the mortality rate, as compared to other operative procedures. Delay in operation and overconservative therapy result in an unnecessarily high mortality rate.

Agglutination and Rh Factor—Lindsey states that cells washed in warm saline solution to remove possible autoagglutinins should be used in typing and matching blood. Before transfusion a patient's serum should be tested against his own cells at ice box temperature to detect autoagglutinins which may cause a post-transfusion reaction. If autoagglutinins are demonstrated the patient should receive only small amounts of blood. If a transfusion is to be given or when a transfusion is to be given in pregnancy or the puerperium, compatibility tests should be made at ice box temperature to exclude Rh agglutinins. In testing the serum of a patient containing autoagglutinins active at room temperature the serum might be erroneously classified as belonging to group O, since it would agglutinate the test cells of groups A and B. Likewise if unwashed cells or cells washed at room temperature are used the serum might be erroneously classified as group AB since the cells would agglutinate in both A and B test serums because of the absorbed autoagglutinin. Similarly no donor would be found compatible if serum collected at room temperature or unwashed cells should be used in cross matching. A true reaction could be obtained only by some process designed to free the cells or the serum of the autoagglutinin: (1) by using serum separated at 0 C, (2) using cells washed several times in warm (40 C) saline solution and (3) carrying out typing and matching reactions in an incubator at 37 C.

Roentgen Features of Scleroderma and Acrosclerosis—Jackman discusses the important roentgen features of scleroderma and acrosclerosis by presenting cases that show most of the important roentgen changes which are calcinosis changes in the osseous system, pulmonary fibrosis (questionable) and esophageal stenosis (occasional). The essential pathologic change in scleroderma is thickening and sclerosis of the collagenous bundles. The disease is not limited to the skin and underlying connective tissue, muscle, bone and fascia are said to participate in the pathologic change. This may explain the occurrence of pulmonary fibrosis and esophageal stenosis. The necrosis of the terminal phalanges of the fingers is secondary to the associated vasospastic phenomena which accompany acrosclerosis. The calcinosis may be explained on the solubility of lime salts in acid and alkaline mediums. These salts are more soluble in acid mediums and remain in solution in normal tissues with a high carbon dioxide tension because of active metabolism. In necrotic tissue there is lowering of the carbon dioxide tension as a result of lowered metabolism. The reaction becomes alkaline and lime salts are precipitated from blood and lymph which diffuse into the area.

Surgery of Spleen in Blood Dyscrasias—Harrison and Stevens review the literature of the last ten years and give a statistical report showing the mortality and life expectancy following splenectomy in splenic meningeal thrombocytopenic purpura and idiopathic. To this they add a report of 63 personal cases. Splenectomy gives the patient with splenic meningeal the best chance for recovery and the earlier in the disease it is performed the lower the surgical mortality and the greater the life expectancy. It is Harrison's opinion that this is the only choice with cirrhosis. The operative mortality should not be more than 10 per cent, some patients have lived twenty years postoperatively. Patients with chronic hemorrhagic purpura who do not respond to conservative therapy should be subjected to splenectomy. Also in acute or fulminating hemorrhagic purpura which does not respond promptly to conservative measures it should be performed before the patient's condition becomes critical. It is important to eliminate infection in the prevention of recurrent purpura. Splenectomy is the treatment of choice in hemolytic jaundice, particularly in children. It is preferable to perform the operation during a remission. In adults splenectomy is not always necessary.

Livedo Reticularis and Vasospasm—Shumacker cites an unusual case of vasospasm of the lower extremities associated with livedo reticularis. Lumbar sympathectomy gave an excellent result and appears to be indicated in cases of this kind. Because of the absence of pain with the uterine contractions of labor in this patient, the possibility of inhibiting painful stimuli from the uterus by interruption of the lumbar sympathetic impulses is being investigated. The patient reacted normally to other painful stimuli. It is not certain whether there was a causal relationship between the excision of the lumbar sympathetic chains and the absence of pain with uterine contractions. From the data available the best explanation of the mechanism of livedo is that there are areas of maximal blood supply in the skin, perhaps from capillary arborizations from central arterioles which enter the skin from below. In these central areas the tone of the capillaries is greater and the blood flow faster than in the surrounding periphery. Either through organic changes in the blood vessels or through vasospasm of the arteries and arterioles supplying the skin, the capillary atony and stagnation of blood flow in the peripheral areas is further increased. This increase causes the livid discoloration in annular rings surrounding central pale areas. The discoloration is intensified by exposure to cold, which further increases the vasoconstriction of the arteries and arterioles supplying the skin. The livid areas disappear or change to pink when vascular spasm is released by warming the body or by sympathetic interruption. Dependence of the affected part similarly brings about some intensification. The persistence of some mottling after warming the body or

sympathectomy is due to the fact that atony and dilatation of the capillaries may be permanent. The disappearance of the livedo on elevation of the affected limb may be explained by the fact that the venules draining the capillary bed in the peripheral annular zones are somewhat dilated.

- *Absorption and Excretion of Sulfonamide Compounds Suspended in Oil: Observations on Animals and on Patients with Chronic Osteomyelitis D. M. Angewine Wilmington, Del—p 186

Sulfonamides in Oil—Suspensions of sulfonamide compounds in soybean, corn, sesame, peanut, cottonseed and olive oil, hydrous wool fat and yellow petrolatum were used by Angewine to observe their local reaction, absorption and excretion following single subcutaneous injections into rabbits, rats, 1 dog and in patients with chronic osteomyelitis. All the oils were commercial preparations not further purified, and of them the largest volumes of drug could be added to and the smoothest suspensions obtained with soybean oil, corn oil and sesame oil. There is a slight separation of oil and drug on standing for a few days, however, the suspensions of sulfanilamide, sulfapyridine and sulfadiazine can be readily remixed with a glass rod, and the suspension of sulfathiazole can be remixed, but with more difficulty. Suspensions kept at room temperature for three months are apparently satisfactory. Sulfanilamide, sulfathiazole, sulfadiazine and sulfapyridine can be suspended in oil in high concentrations. Suspensions of sulfanilamide and of sulfathiazole in soybean oil produced only a slight local reaction in animals when they were injected subcutaneously. In animals a single subcutaneous injection of sulfanilamide, sulfathiazole or sulfadiazine suspended in oil was absorbed at a uniform rate and, depending on the dose, produced a concentration of the drug in the blood for as long as eight days. The excretion of the drug in the urine continued for several days after it had disappeared from the blood. Suspensions of sulfanilamide or sulfathiazole in soybean oil were instilled into the infected sinusal tracts of 5 patients with osteomyelitis. The drug was present in the blood for six days and was excreted for as long as one hundred and thirty-seven days. The sinuses of 2 of the patients healed completely and those of the others improved. This method of therapy appears to deserve a further trial in chronic osteomyelitis and in other types of infected wounds.

Weil's Disease in an Army Camp—Varadi reports the case of a young soldier who contracted Weil's disease while handling a rat trap. Most of the classic features of the disease were present. The disease could have remained undetected, as the localized rash, which appeared on the seventh day of illness, disappeared quickly. There was a rather extensive involvement of the nervous system. For the first day or two there were signs of slight meningeal participation (nuchal rigidity), which subsided rapidly. The knee and ankle jerk were practically absent from the day of admission (fourth day). The ankle jerk reappeared within twelve days and the knee jerk in about a fortnight. Paresthesia of the skin to heat and vibration subsided at about the time the tendon jerks were returning. These sensory changes were most probably due to a polyneuritis. *Leptospiras* were found in the patient's urine and in the kidneys, liver and adrenals of the guinea pig inoculated with the patient's urine. The case is a further proof that whenever an acute febrile illness appears associated with nephritis, severe muscular pain and great tenderness in the muscles of the limbs Weil's disease should be considered. And in the patient's history reveals the possibility of infection by rats, serum treatment should be introduced at once without waiting for the laboratory confirmation of the diagnosis. This treatment it started in the preicteric stage, is decidedly beneficial.

Propamidine in Chronic Wound Sepsis—Bacteriostatic action of amidines unlike the sulfonamides, is not inhibited by the peptones and other constituents of pus and tissue fluids in wounds. Thrower and Valentine determined the local value of these compounds in wound sepsis particularly the action of 4,4-diamidinodiphenylpropane dihydrochloride (propamidine). A watery gel of between 4.5 and 5 per cent of methyl cellulose was selected as a vehicle for the propamidine. The wound was cleaned with isotonic solution of sodium chloride and explored to ensure that the jelly would come in contact with the entire surface. A sterile spatula was used to fill up the cavity to skin level with 0.1 per cent propamidine jelly. The jelly must not come in contact with the edges of the skin. The wound and surrounding area were then covered with two or three layers of impermeable petrolatum gauze and a thin layer of gauze or wool over the petrolatum gauze. On redressing exudate and stale jelly were swabbed or washed out with saline solution and fresh jelly was applied as before. A 0.4 per cent concentration of the drug caused necrosis of granulation tissue and concentrations in excess of 0.1 per cent tended to injure granulation. Full benefit was obtained in ten days. A second course of treatment can be given for recurrence. A satisfactory result may sometimes be obtained when an interval of a week is left between dressings. When redressing was painless and easily

done the dressing was changed on alternate days or, when there was much discharge, even daily. Cultures showed that the streptococcus was the first to disappear and then the staphylococcus. *Proteus vulgaris* and *Pseudomonas pyocyanea* often persisted without appearing to retard progress. Correctly used, propamidine can clear the field of dangerous organisms within ten days and then other necessary measures may be proceeded with.

Propamidine in Chronic Streptococcal Infection—McIndoe and Tilley assessed the value of propamidine in 11 open persistent old wounds secondarily infected by a beta hemolytic streptococcus of open wounds and old burns which had failed to heal with diluted solution of sodium hypochlorite or sulfamylamide, tulle gras and saline solution. One uninfected fresh burn also was treated. The technic employed was that developed by Thrower. In some instances improvement was evident within forty-eight hours of treatment, especially in the more recent infections. Older or more indolent surfaces responded less rapidly but steady improvement occurred in all cases coincidentally with the disappearance of beta hemolytic streptococci. Streptococcus control took place in two to ten days though reinfection requiring a second course occurred several times. The authors did not see irritation of the surrounding skin and necrosis of the granulating surface after more than ten days of treatment. In only 1 such patient was there a mild irritation of the skin. While the beta hemolytic streptococcus was effectively controlled this was not the case with other organisms. In 3 patients subsequent grafts failed partially because of staphylococcal infection. Although healing may take place at a normal rate in the presence of saprophytic and mild pathogenic organisms, a graft may be mechanically lifted from its bed. A 0.1 per cent propamidine in a lanette wax and petrolatum base was superior to a water soluble jelly mixture. The result in the fresh burn was impressive.

Propamidine in Burns—Morley and Bentley treated 7 burns within five hours of the accident, 5 that were treated elsewhere for three or more days and 2 infected areas as preparation for skin grafting with propamidine. Speedy healing of the burned areas without relapse or indolence suggests that streptococcal and staphylococcal infection was effectively controlled. The progress of the burns has been remarkable for the rapidity of separation of slough and the speed of epithelialization. The latter and the mobility of the part throughout treatment combined to produce a minimum of scar tissue and an extremely good cosmetic and functional result. When propamidine was tried as an alternative dressing for areas that had become indolent or infected with sulfonamide resistant organisms infection yielded quickly to propamidine and healing was accelerated. Propamidine appears of value in the early separation of tight sloughs in deep burns by virtue of its apparent property of controlling streptococcal and staphylococcal infection while allowing saprophytic and proteolytic organisms to flourish. These organisms must be controlled by other measures before skin grafting is done.

Murine Typhus in British Soldiers in West Africa—Smith and Evans report the occurrence of 4 cases of murine typhus in Europeans in a West African colony in which the disease has not occurred heretofore. The cases show that the diagnosis not only can be missed because of the mildness of the clinical course but also may be confused by alterations in the Widal reactions due to TAB inoculation and by failure to read agglutination tests as late as the twenty-first day after onset. The typhus occurred in soldiers living under good conditions in a good climate. Their food was liberal. Only 1 was shown to have subtertian malaria parasites in the blood but he gave no history of clinical malaria. The longest time spent on the West Coast of Africa by any of the 4 men was ten months. The first patient could not well have been more severely ill and survived the picture he presented conformed closely to the classic descriptions of epidemic typhus. The disease in the other 3 was less severe. These 3 men were not only from the same billet but actually from the same bed each patient moving into the infected bed as the previous occupant was admitted to the hospital. Common to all 4 were a dusky cyanotic bluish tint to the face on initial clearing during the day, delirium

intestinal disorders and diarrhea in 1 case, after prolonged exposure to cold in another, and in the course of a chronic infection or following acute infection in 3 cases. The symptoms appeared suddenly in some and slowly in others. Anemia motor and sensory disorders, especially slight paralysis of the arms, more or less acute paralysis of the legs, signs of pyramidal lesions, dysesthesia and muscular pain occurred in all cases. Anemia appeared either before or after the appearance of the neurologic symptoms. It was of the hyperchromic type in patients with the acute onset of the neurologic signs and of either the hypochromic or normochromic type in patients with a mild type of the disease. Early or recurrent mental disorders with hallucinations or of the type of dementia paralytica occurred in cases in which the disease had a sudden onset. The blood Wassermann reactions and the cerebrospinal fluid Wassermann tests were negative in all. The colloidal gold test showed a deviation of the curve to the left, similar to that observed in syphilis and in multiple sclerosis. Early liver and vitamin B₁ therapy controls anemia, mental symptoms and the degenerative process of the nervous tissue. The author found at a necropsy that the posterior and lateral columns of the cord were the localizations of acute degeneration while the cerebellum and the cerebrum exhibited a moderate involvement. The author believes the disease to be caused by an exogenic toxin which causes selective degeneration of the nervous tissue in the resistance of the latter is diminished because of avitaminosis A and B₁.

Immediate Mobilization After Operations on the Digestive Tract—After more than two thousand operations on the digestive tract Gonzalez Bueno concluded that postoperative care could be simplified. The absence of postoperative complications made him decide that the patients should leave the operating table on their own feet. He reviews reports on a series of seventy-four consecutive laparotomies in which the postoperative treatment was ambulatory. The operations were on the stomach, the biliary tract, the liver or the intestine. To make possible immediate postoperative mobilization the patient must be carefully prepared for the operation. He should be kept in bed for twenty-four hours before and should be subjected to careful clinical examination, including laboratory tests. The type of anesthesia is an important factor. The author uses a local circumscribed anesthesia that involves only the abdominal wall. The surgical technic must be exact and delicate but rapid. After the operation the patients put on their own clothes and left the operating room on foot. For two days they were kept in special rooms where they sat in easy chairs. They were urged to move their extremities frequently and take deep inspirations. Some even went for a walk. After two days they returned to their wards where they were comparatively active. Pulse rate, blood pressure, urination and intestinal function were carefully watched. No great changes were observed. A blood examination was made daily. The patients were all discharged in the course of ten days. There were no pulmonary, circulatory or renal complications. The intestinal motility and the renal function were quickly normalized. There were no gastrorrhagias, hematomas or dehiscences. The ambulatory postoperative treatment has also a beneficial psychologic effect. It is not possible in all cases nor can it be carried out by an inexperienced surgeon.

Atypical Localization of Rheumatic Nodules—Lorente and Marina point out that rheumatic nodules, particularly in children, are localized most frequently in the periarterial tissues of the extremities. They recently observed a girl aged 11 who had active rheumatic endocarditis with mitral stenosis and on whose abdomen were two curious little lumps. A history of rheumatic pains and the localization of the nodules in the subcutaneous tissue suggested their rheumatic nature. A biopsy confirmed it.

Blood During Pregnancy—Merchante determined in 46 women the hemoglobin by the ferrometric method of Wong, the volume of erythrocytes by the method of Wintrobe and the number of erythrocytes per cubic millimeter. The results show that the hemoglobin content, the volume and the number of erythrocytes diminish from the beginning to the end of pregnancy. The hemoglobin value shows a slight increase in the second month; there is an abrupt decrease in the third and a slower one thereafter with an increase in velocity in the eighth and a slight ascent in the ninth. The values fluctuate between 12.55 Gm per hundred cubic centimeters in the first month and 11.45 Gm per hundred cubic centimeters in the ninth, temporarily reaching about 13 per hundred cubic centimeters in the second month. The erythrocyte count per cubic millimeter decreases progressively from the beginning to the end of pregnancy. At times there is a slight relative increase in the fourth month. The figures fluctuate between 4,358,000 during the first month and 3,572,000 in the ninth. The total volume of erythrocytes decreases progressively from 42.42 per cent during the first month to 38.96 per cent in the ninth; occasionally there is a slight increase during the second month.

Roentgen Therapy of Glaucoma—The Terrizzanos employed roentgen irradiation in 10 cases of glaucoma. One was of traumatic origin, 6 were painful and chronic, 2 were hemorrhagic and in 1 the glaucoma was accompanied by hypertensive iritis. All were improved. Pains and lacrimation either disappeared or improved. Keratoconjunctival inflammation disappeared rapidly and the authors observed no disagreeable reaction. Only 1 of the 10 patients had a relapse after seven months, which could be counteracted by two new irradiations. The authors suggest that the effect of roentgen therapy is due to complex action on intraocular osmotic phenomena, modifications in the capillary circulation, tissue ionization, variations in the acid base and colloidal equilibrium and a direct action on the neural terminations. Tension of 1-1.5 kilovolts with 10 milliamperes at a distance of 50 cm and filtration through 0.25 mm of copper and 1 mm of aluminum gives the best result.

Book Notices

The Hemorrhagic Diseases and the Physiology of Hemostasis By Armand J. Quick, Ph.D., M.D., Associate Professor of Pharmacology, Marquette University School of Medicine, Milwaukee. Cloth Price, \$5. Pp. 310 with 21 illustrations. Springfield, Ill. and Baltimore, Charles C. Thomas, 1942.

The past five years have witnessed great clarification in the mysteries surrounding the various problems relating to blood clotting. In this period a number of seemingly unrelated investigations have converged, newer knowledge regarding prothrombin and methods for its detection, discovery of the antihemorrhagic vitamin K, purification and therapeutic use of heparin, and discovery in sweet clover disease of cattle of the hemorrhagic factor dicumarol. In these investigations the name of Quick has constantly loomed large and it is therefore fitting that the first authoritative monograph on the physiology and clinical manifestations of normal and abnormal hemostasis should have been written by this Marquette University investigator.

The book is distinguished by its thoroughness and clarity, and above all by its wisdom. Well and simply written, it fulfills a long felt need in grouping together in separate chapters the many accumulated bits of knowledge regarding thrombin, prothrombin, thromboplastin, fibrinogen, platelets and anticoagulants. The references, which are unusually complete, are alphabetically grouped at the end of each chapter.

Discussions of physiologic principles are followed by chapters dealing with such clinical conditions as thrombopenic purpura, hemophilia and hypoprothrombinemia, and the uses of heparin and dicumarol. Although a thoroughgoing discussion and painstaking review of the literature distinguish these chapters as well, they suffer somewhat from the author's primary concern with the laboratory rather than with the clinic. Particularly with thrombopenic purpura and hemophilia there is too much reliance on the literature (this is often a bad tendency since "the literature" is made up of good stuff and bad). Also some of the author's pet theories, e.g. a histamine disturbance in purpura and a simple thromboplastin defect in hemophilia, are perhaps unduly emphasized. There is increasing evidence that idiopathic thrombopenic purpura is primarily a splenic dysfunction with remote possibly hormonal inhibition of platelet formation from megakaryocytes in the bone marrow. As regards hemophilia, the clearest experiments of F. H. L. Taylor and his associates at the Thorndike Memorial Laboratories in Boston are dismissed with scant notice. Whether hemophilia is primarily a thromboplastin deficiency or an abnormality in the euglobulin fraction of the plasma is still not entirely settled, perhaps both groups of investigators are right.

These criticisms might be classed as captious, for the book is not only authoritative and thorough but respectful of the large literature and not unmindful of the historical roots of a particular subject. The format, typography and printing are quite in keeping with the general excellence of the work, which is completed by an appendix containing methods for determination of the coagulation time, bleeding time, clot retraction, platelet count, prothrombin and fibrinogen together with methods for assay of thromboplastin, thrombin and heparin. The book is highly recommended for use in general hospitals and clinical laboratories. Collaboration with a clinical investigator might be desirable in a second edition.

Dark Legend: A Study in Murder By Frederic Wertham, Senior Psychiatrist, Department of Hospitals, New York City. Cloth Price, \$2.75. Pp. 270. New York: Duell, Sloan & Pearce, 1941.

This is a popular yet authentic account of a 17 year old matricide. His own story of the events leading to the murder, of the crime itself and the author's analysis of the crime are given. The case is that of an Italian boy who murdered his mother, consciously motivated by his feeling that by her sexual promiscuity she had dishonored the family and the boy's deceased father. The author proceeds to show that more important unconscious motives determined the criminal act. The book is an excellent contribution to forensic psychiatry. The author

shows the dilemma of the psychiatrist faced with the rigid legalistic conceptions of insanity on the one hand and his convictions that as a physician he must regard the boy as ill, must understand the nature of this illness and if possible initiate steps leading to a possible cure. His careful diagnostic discussion of the case will be of interest to all physicians. Having ruled out the major psychoses, he suggests that clinical patterns like that presented in his case could be called "catathymic crises," a circumscribed mental disorder in which the central manifestation is the development of the idea that "a violent act—against another person or oneself—is the only solution to a profound conflict whose real nature remains below the threshold of the consciousness of the patient." The book is written in popular style and the author offers as background for his observations numerous references to the tragedies of Hamlet and Orestes, in which he shows that the reactions of his young patient to his conflictual situation are in many precise respects those of Hamlet or of Orestes. In other words he makes it clear that matricide is based on unconscious motivations, better recognized thus far by the poets than by the professional students of human behavior, at least until recent years. This book should be in every medical library.

Orthopedic Nursing: Content and Method of the Teaching Program in Schools of Nursing By Carmella Calderwood, R.N., Consultant in Orthopedic Nursing, National League of Nursing Education, New York. Paper, Pp. 61. New York: Joint Orthopedic Nursing Advisory Service of the National Organization for Public Health Nursing and the National League of Nursing Education, 1942.

Too little consideration has been devoted to orthopedic instruction during the training of student nurses. Satisfactory care of the orthopedic patient requires special knowledge of technique and procedures not possessed by the average graduate nurse. This small pamphlet, published and distributed by the Joint Orthopedic Nursing Advisory Services of the National Organization for Public Health Nursing and the National League of Nursing Education, is a much needed outline of methods and materials which should be available to those who are responsible for the teaching program in every school of nursing.

Aids to the Investigation of Peripheral Nerve Injuries Medical Research Council Nerve Injuries Committee. M. R. C. War Memorandum No. 1. Paper. Price 60 cents, 2s. Pp. 48 with 74 illustrations. New York: British Information Services, London: His Majesty's Stationery Office, 1942.

As an aid to the diagnosis of lesions of the peripheral nerves, this pamphlet illustrates in a series of excellent pictures the actions of the various muscles of the body. With the accompanying diagrams giving the general course of the principal nerves of the body and the muscles which they supply, a complete examination of the peripheral nervous system can be easily carried out. The pictures are exceptionally clear and the diagrams excellent. The material here presented in a compact form could be found only in numerous textbooks. It was prepared by the staff of the department of surgery of the University of Edinburgh.

Fundamental Principles of Bacteriology By A. J. Salle, B.S., M.S., Ph.D., Associate Professor of Bacteriology, University of California, Los Angeles. Second edition. Cloth. Price \$4. Pp. 643 with 213 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1943.

This edition contains more textbook material than the previous edition. The laboratory procedures have been taken out of the second edition and included in a separate manual prepared by the author. Numerous chemical formulas are given especially in the chapters on biologic stains, disinfection and disinfectants, enzymes of bacteria, the respiration of bacteria, protein decomposition, industrial fermentations, the bacteriology of water and the bacteriology of soil. These excellent chemical illustrations make it unnecessary to consult textbooks of chemistry for a complete understanding of the subjects. The book is not a treatise on medical bacteriology since only three of the twenty-seven chapters are devoted to this field. The fundamentals of bacteriology are well covered and the book can be heartily recommended to students in basic courses in bacteriology and to physicians who wish to bring their knowledge of bacteriology up to date.

Queries and Minor Notes

RAPID TREATMENT OF EARLY SYPHILIS

To the Editor—In *Collier's* April 10, 1943 it is stated that maphorsen used three times a week with bismuth for eight weeks produces cures of syphilis. Is this true or is it like when arsenophamine came in use and it was considered that one dose produced a cure? How often should maphorsen be used, three times a week or one time a week? Has any change of time been accepted for cures or is the eighteen month treatment still considered necessary?

D. D. DeNeen, M.D., Los Cruces, N. M.

To the Editor—In the April 10 issue of *Collier's* there is an article by J. D. Ratcliff in regard to treatment of syphilis in Louisiana. He states that syphilis is cured in two months by three doses of maphorsen weekly plus one injection of bismuth weekly. Has this outline been tried long enough to know that it will give complete cure in this short time? And are these two given at the same time?

W. L. Boswell, M.D., Clarendon, Ark.

ANSWER—Eagle and Hogan have attempted to approach the treatment of syphilis in man by experimental study of rabbit syphilis. While a review of all the work they have done would be impossible in this reply, it may be stated that even though rabbit syphilis is not necessarily human syphilis a great number of the truths applicable to the one will apply to the human being and vice versa. Among other things they have found that until the time limits within which infectious relapse may occur in the syphilized rabbit have been more thoroughly defined the absolute curative dose of arsenicals in rabbit syphilis cannot be determined by lymph node transfer. Even data as to the relative efficacy of various treatment procedures must be interpreted in the light of the time allowed to elapse between treatment and the following lymph node transfer. Their studies showed that, six months after treatment in a large series of rabbits apparently cured at three months as judged by lymph node transfer, 37 per cent of them were still infectious. Apparently the disease was actually quiescent at three months after treatment but not cured. And may there not be a lesson in this in considering the treatment of human syphilis?

As the result of their studies on rabbit syphilis and of the conclusions that they felt justified in drawing it has been suggested by them that an intravenous injection of an arsenical be given three times a week to human beings and that an intramuscular injection of a bismuth preparation be given once a week. This work has been carried on for an insufficient length of time to allow any one to draw definite conclusions.

In 1937 Thomas and Wexler increased the number of injections of mapharsen from one to two a week at their clinic in Bellevue Hospital, and by 1938 they had raised the number to three a week for a period of four weeks, for all patients with early infectious syphilis. In the light of the publicity that has recently been given to the intravenous drip treatment they determined to attempt rapid massive treatment of syphilis without the continuous drip, as their facilities at Bellevue did not easily allow the latter. They now combine their intravenous injections of an arsenical preparation once a day for ten days with fever treatment achieved by an intravenous injection of typhoid-paratyphoid vaccine given on the second, fourth, sixth and eighth days. They feel that their results with this form of therapy for early syphilis are quite satisfactory. Naturally all the patients are hospitalized. They are studied carefully and everything is done for them by experts in the field.

Both these techniques indicate experimental forms of treatment of acute syphilis that are being employed at present. Moreover the intravenous drip treatment is still being employed in certain treatment centers. Naturally none of these forms of therapy are yet ready to be carried out by the inexperienced. They include far more than simply the giving of an injection. The physician attending such cases must be well acquainted not only with the diagnosis of the disease but also with the handling of any emergencies that may arise where such heavy therapy is being employed. Also he must be competent to follow the patient afterward and to interpret any unusual reactions or manifestations that appear. Unfortunately, the treatment of acute syphilis is not yet simple.

HAND MADE AND MACHINE MADE CIGARS

To the Editor—What, if any deleterious effects have been noted in smoking cigars made by the dirty paste hand method as compared to the precision like and sanitary machine produced cigars? Ph G. New York.

ANSWER—For centuries the manufacture of cigars represented a highly skilled and artistic craft, whose products were highly prized. When machine made cigars were first introduced they were sold at lower prices because of the general prejudice in favor of the hand made variety. The individual selection, orientation, packing and sealing of the filler and wrapper in hand made cigars were especially emphasized.

Within the past generation energetic attempts have been made by advertising agencies to reverse this popular attitude. The advertising has particularly stressed the esthetically repulsive as well as hygienically unsound practice of licking the edge of the wrapper leaf or the tip reportedly practiced by many of the skilled hand workers. The survival of tubercle bacilli on tobacco leaf was demonstrated by Kerez nearly half a century ago and the occurrence of tubercle bacilli in cigars so made has been reported repeatedly since. The high incidence of tuberculosis among cigar makers which was noted by a number of workers a generation ago, emphasized the danger from that source.

The use of a paste or gum applied with a brush which is the common method of sealing hand made cigars today may involve the possibility of contamination with organisms from the paste or from the hand of the workers but tubercle bacilli are not so apt to be transmitted in this way. Other organisms may be demonstrated in cigars prepared in this way but their viability and virulence are more apt to be eliminated by drying and standing before the cigars are actually used. Accordingly, disease due to pyogenic cocci, *Treponema pallidum* and other possible vectors has yet to be traced to contamination during the manufacture of cigars.

The hazard from infection through hand made cigars need not be exaggerated. The danger of immediate transfer of infection from the passing of a cigar from mouth to mouth is apparently much less than with the more frequently observed practice with cigarettes and pipes. But it is questionable whether the esthetic appreciation of the traditional art of the cigar maker outweighs the esthetic objections to the uncleanness traditionally associated with his product.

MULTIPLE DOSES OF MAPHARSEN FOR EARLY SYPHILIS

To the Editor—In view of the recent so called five day treatment for early syphilis by the continuous administration of mapharsen would it be good practice to give mapharsen in the usual dose twice or three times a week in early syphilis instead of once a week? If so has there been any work done using this plan of treatment and where could I find any literature pertaining to this particular question?

U. S. Hargrove, M.D., Baton Rouge, La.

ANSWER—Yes, there have been many attempts to use mapharsen more frequently than once a week in the treatment of early syphilis. For example, the attempt has been made to give an injection of mapharsen daily for a period of twenty or thirty days. Naturally the reactions were numerous enough so that this practice has since been discontinued. Thomas and his co-workers (Cere-

bral Reactions Associated with Massive Mapharsen Treatment of Early Syphilis. *Am J Syph, Gonorr & Ven Dis* 26:529 [Sept.] 1942) have done a great deal of work along this line, trying various methods of employing arsenicals in early syphilis, as have also Eagle and Hogen (Intravenous Drip and Other Intensive Methods for Treatment of Early Syphilis, *Science* 95:360 [April 3] 1942). It may be concluded that it has been found good practice to give as much arsenical therapy as is safe in the early stages of the syphilis. Agnew Cole (Syphilotherapy: Recent Advances, *Brit Journ Vn*, Sept. 27, 1941, p. 1091) has suggested the use of more frequent injections than once a week in the early stages of syphilis. In fact, in many of the syphilis clinics it has been the practice for several years to use multiple doses of mapharsen for the first few weeks of treatment. It should be understood that nearly all this work has been done in university clinics or in syphilis clinics under the best of conditions where every facility is at hand to study the patient and to observe reactions.

As yet it is too early for such therapy to be employed on an extensive scale in private practice. Naturally it is to be hoped that as a result of all these observations much good will be achieved in the way of better arsenical therapy for early syphilis.

CONTRAINDICATIONS FOR DIETHYLSTILBESTROL

To the Editor—Kindly give me the contraindications for the use of diethylstilbestrol and any possible harmful effects of its use.

J. Howard Gould, M.D., Ridgewood, N. Y.

ANSWER—Diethylstilbestrol is the potent estrogenic substance made synthetically. The contraindications for its use are the same as for the natural estrogens. These include excessive menstrual flow, prolonged menstrual flow, the presence of any neoplastic disorder in the genitalia or in the breast, and some authors think the presence of neoplasia in any part of the body. The latter is debatable. In addition, diethylstilbestrol and its derivatives have an apparent tendency to cause nausea and emesis in a considerably larger number of patients than suffer the discomfort from the use of even very large doses of the natural estrogen. This is a temporary phenomenon and is apparently produced not in the gastrointestinal tract but centrally. Occasional cases of a skin reaction have been reported. Used within the limits of dosage which are conventionally necessary for the control of climacteric symptoms for the relief of breast discomfort post partum or for the treatment of vaginitis in the preadolescent or the postmenopausal patient, there is no obvious harm if nausea and emesis do not occur.

BLOOD FOR TRANSFUSION FROM EPILEPTICS

To the Editor—The question has been raised as to whether or not there is any contraindication to using the blood of patients with epilepsy for transfusion into nonepileptic persons. What would be the proper answer to a group of epileptic patients who have volunteered to donate blood to the Red Cross and other similar organizations?

Willard W. Dickerson, M.D., Cara, Mich.

ANSWER—Epilepsy is not an infectious disease and, except immediately after a convulsion, the blood of physically normal patients is normal. Therefore, provided adult epileptic patients are in proper physical condition, the use of their blood for transfusion purposes is not contraindicated. If part of a blood pool, the amount of contained phenobarbital or phenytoin sodium would be infinitesimal. Probably the loss of a pint of blood would not increase seizures, but if the institutional diet is relatively poor in protein the patient's diet and hemoglobin should receive special attention. Because epileptic persons are denied service in the armed forces and to a large extent in industry, the opportunity to participate in supplying blood for the common good should be beneficial to their morale. Inmates of hospitals and prisons would seem to be a logical source of blood which is to be used in the war effort.

HONEY FOR INFANT FEEDING

To the Editor—Will you kindly advise me regarding the use of honey for infant feeding.

M.D., Vermont

ANSWER—Honey consists of a mixture of sugars, chiefly levulose and dextrose with some cane sugar. It was formerly used as the carbohydrate addition to any artificial mixture in amounts of 1 ounce in a twenty-four hour feeding, although its ease in digestion makes it possible to use more of it than of other carbohydrates. It was not believed that it possessed any special advantages over other forms of sugars and was thought to have allergic tendencies for some infants. Recently it has come into use again. Lahdensuo (*Acta Soc med fenn duodecim*

15:1 [series B, No. 3] 1931) reported that it decreased diarrhea and vomiting, and Knott, Shukers and Schlutz (*J Pediatr* 19:485 [Oct.] 1941) that it seemed to have a beneficial effect on calcium retention.

EFFECT OF MALARIA ON EPILEPSY

To the Editor—Does malaria exert a healing effect on epilepsy? Hippocrates wrote (*Epid* 1, sect. III) "The least dangerous, mildest and most prolonged of all is quartan fever, for it is not only such in itself but it also removes other types of dangerous diseases," and (*Epid* VI, sect. VI 5) "Patients suffering from the great disease (epilepsy) not affected by quartan fever, if they become affected by it, then they are freed from epilepsy." Also Aphor. V, 70, "Persons attacked with quartans are not readily attacked with convulsions, or if previously attacked with convulsions, they cease if a quartan supervenes." Rhaphos also testifies to this truth. Reference: Max Neuberg, *The Doctrine of the Healing Power of Nature Throughout the Course of Time*, translated by L. J. Boyd, New York.

Fred Stenn, Lieut., M.C., A.U.S.

ANSWER—These references to ancient authors are of great interest historically, but the observations presumably were based on uncontrolled observations. The inadequate modern observations on the subject have been reviewed by Gladys C. Terry (*Fever and Psychoses*, New York, Paul B. Hoeber, Inc., 1939). She gives three references to articles dealing with the effect of natural malaria infection and six references to the effect of artificially induced malaria. Presumably any favorable results which may be observed are due to the fever and not to the plasmodia. The author also summarizes the influence on seizures of infections other than malaria, and of hyperpyrexia induced by typhoid or sulfur or by diathermy. Results which were at least temporarily favorable were reported by the majority of authors, but the smallness of groups observed, the lack of control material and the tendency of workers to withhold publication of "negative" results do not warrant the drawing of conclusions. The subject deserves further study. In children fever oftentimes induces convulsions.

REMOVAL OF FISH HOOKS

To the Editor—Some time ago in a fishing magazine I saw the following advice as to the method of removing a fish hook from one's anatomy. I should like to say that I don't agree with the method at all, owing to the fact that the barb in reverse would be most likely to do severe damage to nearby nerves and vessels. I agree with just the thing they do not agree with, that is the "push through" method, which I understand to mean to push the point of the hook through at the nearest point to the surface and then cut the barb off and slip the hook out. I should like to have your opinion on this matter. This is a quotation: "If you run a hook into your finger, beyond the barb, while going fishing or going over your gear this winter, forget that old gag about cutting it off short and pushing it through. Instead, take a pair of small nosed pliers, take a good hold on the hook yourself or have some one officiate for you, and yank. We have had plenty of hooks taken out of our own anatomy this way and we can vouch for its efficiency. Even big hooks come out without doing any real damage. Personally we do not go for that 'push through' technique at all at all."

R. H. McPherron, M.D., Chicago

ANSWER—By all odds the "push through" method is the best one for the removal of a fish hook in which the barb has gone in beneath the skin. Circumstances can conceivably arise in which it would require pushing the fish hook through a considerable distance by a curved route before the barb emerges from the skin. When this occurs, it would seem better to make a small incision down to the barb before pulling it out backward.

AMPHETAMINE FOR OBESITY

To the Editor—In reply to a query regarding the use of amphetamine and its dextroisomer in obesity published in *The Journal*, March 6, 1943, page 796, it is stated ambiguously that the d form "is said to be two to four times more active than the levo form or the dl mixture." Alles (*Univ California Pub, Pharmacol* 1:129, 1939) showed that the optical isomers are equipotent in their various peripheral actions, including that on the rabbit ileum; this equivalence of action has been confirmed (Emerson, *G. A. J. Pharmacol & Exper Therap* 76:11 [Sept.] 1942) for blood pressure in dogs. Alles's finding of a greater central stimulant action of the d form, two to four times that of the l amine or one and a half to two times that of the racemic, has been noted also in man (Prinzmetal, Myran, and Alles, *G. A. J. Proc Soc Exper Biol & Med* 12:206 [Oct.] 1939), but the equivalent sympathomimetic of the isomers does not appear to be as widely recognized. If the action in obesity depends entirely on central effects, through influencing appetite, the d form is likely to be more potent though not necessarily preferable to the racemic in the absence of cardiac disease or hypertension. Dennis Jackson's book *Experimental Pharmacology and Materia Medica* (St. Louis, C. V. Mosby Company, 1939) includes directions for studying effects of amphetamine on hunger contractions in decerebrate pigeons, but to my knowledge there are no published results of this technique.

THE GENESIS AND RESOLUTION OF PULMONARY TRANSUDATES AND EXUDATES

CECIL K. DRINKER, M.D.

AND

MADELEINE FIELD WARREN, PH.D.

Dean and Professor of Physiology and Assistant Professor of Physiology, respectively, Harvard School of Public Health
BOSTON

The existence of pulmonary edema is one of the first conditions that medical students are sure they have found. Listening to the chest in cases of cardiac decompensation, one hears rales of varying magnitude and as one progresses toward the bases of the lungs the characteristic signs of edema may be lost. The student being preternaturally alert, says at once to himself and to nearby nurses "Ah, a pleural effusion!"

Forthwith a new issue arises. To tap or not to tap—that is the question! Having been a medical house officer and a medical resident with a surgical complex kept under with difficulty, I usually found a reason for trying to drain this abnormal collection of fluid and when I scored heavily in my collection I was correspondingly gratified. That the fluid in question reaccumulated in a few hours did not bother me. I had done something positive, something which could be shown as action in the attempt to cure a sick patient.

ANATOMY AND PHYSIOLOGY OF THE LUNGS

What, then, can one say as to the reasons why this patient's lungs and pleural sacs filled with fluid and his access to oxygen became less and less?

Let me call attention first to a few bits of anatomy and physiology. The lungs of man are so organized as to provide astonishing ability in the meeting of sudden strains. A healthy young adult can readily increase his pulmonary ventilation from a resting minute volume of 8 liters to 125 liters during exercise and with this change his cardiac output may rise from 5 liters a minute to perhaps 20 liters a minute.

In spite of this astonishing adaptability the lungs of man and of mammals are a critically vulnerable link in efficiency in the sense that with each cardiac systole the lungs receive from the right ventricle as much blood as the left ventricle pumps out to the body as a whole. Ordinarily the lungs are not a reservoir of blood though, if the heart is failing they may become so. Let us trace the physiology of the development of pulmonary edema, one of the most frequent of clinical experiences.

The lungs possess a blood capacity in terms of instant cardiac output equal to that of the entire body. Furthermore, many measurements of the pressure in the pulmonary artery of dogs and cats have been singularly uniform for the species. Also the effects of measures designed to increase the pressure in the pulmonary artery such as the injection of ephedrine or very considerable augmentation of the blood flow into the heart cause comparatively little change in pulmonary arterial pressure. These facts mean that in the ordinary course of human experience when you run up a long flight of stairs in order not to be unduly late for a class or when you find yourself in one of those interminable deuce sets in tennis—when you do not want to go on and cannot stop—your peripheral or general arterial blood pressure rises but the pressure in the pulmonary vessels is little changed.

No one has measured the pressure in the capillaries of the lungs. It is an intriguing problem. Landis¹ summarized his direct measurements of capillary pressure and all of us know that under continuous intratracheal insufflation with the lungs quiescent but oxygen supply adequate one might measure pulmonary capillary pressure. Yet the figure obtained would not be satisfactory since the lungs would not be in motion and the negative pressure in the chest which is a fluctuant factor would be absent.

I have said that under the usual experiences of exercise in which systemic blood pressure is increased and blood is shunted to the active muscles pulmonary blood pressure rises insignificantly. During the past seventy-five years many investigators have striven to show that the pulmonary circulation is under some sort of vasomotor control. They have not succeeded and the reason for this failure rests in the very nature of the pulmonary oxygenating mechanism. As far as is possible the lungs must receive and oxygenate all the blood brought to them. This is accomplished by adjusting the breathing and by letting the increased blood flow spread passively through a capillary bed great enough to carry all the blood that can be sent to it even under the most extreme conditions of cardiac output. This simple fact is one of the fundamental conceptions of clinical physiology and we may now attempt to explore its implications.

The problems of the formation of pulmonary exudates and transudates are complicated by our dependence for knowledge on sections of dead lungs. We are almost of necessity preoccupied by what is seen in the alveoli and forget that the fluid which escapes from the blood capillaries must first of all be interstitial must to a degree at least thicken the alveolar partitions.

which normally are just great enough in cross section to contain the pulmonary capillaries and nothing else. Even the lymphatics do not extend into the alveolar wall past the very beginning of the respiratory portion, the atrium. It is clear that any foreign material in the alveolar wall must interpose a barrier to exchange of

FIG. 1—Diagram of alveolus, blood capillary and lymphatic in the human thorax.

gas. I believe this fact was first thoroughly or better generally appreciated at the time of the initial gas attack in the last war, when the Germans used chlorine at Ypres. Obviously, an increase in the interstitial fluid of the lungs cannot long remain out of the alveoli, and with alveolar and bronchiolar filling by transudate or exudate the individual is progressively separated from his air supply.

Let us return now to normal matters. On account of the vast extent of the pulmonary capillary bed and the great elasticity of the lung tissue, it is probable that the pressure in the pulmonary capillaries is low—let us guess around 5 to 10 mm. of mercury instead of 20 mm. of mercury for typical systemic capillaries. The colloid osmotic pressure of the blood going through the lungs is, however, normal and much higher than the capillary blood pressure. The situation to be discussed is shown diagrammatically in figure 1.

Clearly the arrangement found in the lungs makes for dryness. The hydrostatic pressure tending to force fluid and solutes out of the blood capillaries, is probably well below the osmotic pressure of the blood proteins, which causes absorption of water. It would seem that if the capillaries of the lungs resembled those in other parts of the body there would be little leakage of proteinized fluid from the capillaries and consequently no normal use for the lymphatics of the lungs. But hardly any essential part of the mammalian body has a more profuse supply of lymphatic vessels, and, especially in man, lymphoid tissues—both unorganized collections of lymphocytes and more significantly definite lymph nodes—are extraordinarily numerous.

In 1940 we² isolated the lymph drainage from the heart of the dog, collected cardiac lymph and showed that the flow and composition of this lymph could readily be correlated with such straightforward factors as increased cardiac output and anoxia. As is so often the case, during active experimentation other possibilities were evident—lymphatics near the cardiac vessel—and it seemed that these must have come from the lungs. It was a welcome sight, since long before a whole year had been spent in trying to collect lymph from the lungs. A few times a bloody fluid was secured, which was certainly lymph but which had been rendered highly abnormal by the clumsiness of our operative approach.

Today it is easy to collect lymph from the lungs alone, but to do it with absolute certainty the anterior

mediastinum must be opened under artificial respiration. There is an alternative to this formidable operation. If the right lymphatic duct is cannulated under natural breathing one obtains pulmonary and cardiac lymph. In an experiment in which anoxia is avoided and cardiac output is shown to remain constant or to fall it is reasonable to assume that increase in lymph flow from the right duct comes from the lung or is the result of experimental manipulations aimed at the lungs alone. The anatomy essential to support this conclusion is shown in figures 2 and 3. In figure 2³ the heart and great vessels are shown from the front. The right lymphatic duct enters the right subclavian vein above a lymph node, which is quite constant in position. Two other nodes are found between the superior vena cava and the aorta. The lymphatics in this chain drain the heart and lungs and enter the right lymphatic duct. For simplicity the vessels involved are shown singly, but a number of afferent lymphatics enter each node. With experience one learns to distinguish the smaller cardiac lymphatic passing to the upper node from the numerous lung vessels. Figure 3 shows the lymphatics of the lungs from the rear, it is clear that drainage from both lungs goes to the right lymphatic duct. Only the upper part of the left lung supplies lymph to the thoracic duct.

A final point relative to the right duct in the dog is the fact that in at least half the animals in which the right duct has been cannulated chyle has flowed freely from it. This fact has not been realized by the biochemists who have attempted to measure fat absorption by means of thoracic duct lymph, since in many cases an almost equal amount of chyle enters the blood on the right side and has been interpreted as direct blood absorption of fat.

FIG. 2—The lymphatic drainage of the lungs of the dog, showing the heart, lungs and great vessels viewed anteriorly. The superior vena cava is the prominent landmark. On the right there is a single node not far below the subclavian vein. To the left of this vessel two other nodes are usually found, and from the upper one an inconstant vessel may occasionally cross to the thoracic duct.

THE FORMATION OF TRANSUDATES

From what has been said it is easy to see that in studying the formation of pulmonary transudates and exudates two methods of attack may be employed. In

² Drinker, C. K., Warren, Madeline F., Maurer, F. W., and McCarroll, Jane D. The Flow, Pressure and Composition of Cardiac Lymph, *Am. J. Physiol.* **130**: 43 (July) 1940.

³ Warren, Madeline F., Peterson, Delores K., and Drinker, C. K. The Effects of Heightened Negative Pressure in the Chest Together with Further Experiments on Anoxia in Increasing the Flow of Lung Lymph, *Am. J. Physiol.* **137**: 641 (Nov.) 1942.

many dogs the right lymphatic duct may be cannulated without opening the chest and the output of the heart and the oxygenation of the blood followed constantly. If these things are done and the lymph from the right duct does not contain chyle, what one collects comes,

Fig 3—Illustrating a fact found in almost all cases—that lymph from the lungs drains ultimately to the right side. It is a rear view of the lymphatic system and lungs of the dog.

in the main, from the lungs and represents practically the total lung delivery at the moment.

In order to follow the production of pulmonary transudates I shall start with a simple experiment. In figure 4 such an attempt is shown. In this case the right lymphatic duct was cannulated and the lymph found chyle free. Through a tracheal cannula the dog, anesthetized with soluble barbitol, breathed pure oxygen against no resistance. At the end of an hour and a half lymph flow from the right duct was 11 mg a minute and, as is usual, contained a few red blood cells. The breathing was then shifted, by turning a three way valve, so that inspiration was made difficult by cotton wool resistance. At the height of inspiration intrathoracic negative pressure reached 56 mm of mercury. The flow of lymph increased at once and the lymph became bloody.

This seems like an obvious finding, but it happens to be particularly important today, when many of us are working on different sorts of masks without much knowledge of what abnormal resistance to breathing may accomplish. In 1933 Yamada⁴ made pleural punctures on several hundred normal Japanese soldiers. He obtained fluid from 29 per cent of his subjects, it had been at rest, and from 70 per cent following severe work. The lesson of this observation and of our experiments rests in the fact that severe respiratory movements, which increase negative pressure in the chest, will tend to produce pleural and pulmonary exudates even if oxygen lack is avoided, and anoxia as you shall see, is another potent cause of pulmonary

edema. Yamada's observations are, I think, common to us all. Who of you have failed to notice that, if you push yourselves too hard physically, you begin to cough and what you bring up is a watery salty fluid which is not disagreeable, but you know it is not normal and you have extended yourself too far.

In a person with cardiac decompensation there often develops a collection of fluid in the pleural sacs and with this collection there are abundant signs that his lungs are soggy from extravascular fluid. These situations are thought of as being due to increased pressure in the pulmonary vessels. I doubt this explanation. I have often increased pressure in the pulmonary capillaries by gradual compression of the pulmonary veins but this has been done in normal animals with entirely healthy hearts. One can readily force excessive leakage of fluid in the course of such experiments, but the right ventricle is capable of sustaining high pressures for some time and so forces fluid out of the capillaries rather slowly. In the usual case of cardiac decompensation, with valvular heart disease, matters progress gradually. Consider whether dyspnea constantly tending to draw fluid from the pulmonary capillaries by increased negative pressure in the chest, together with progressive anoxia, is not an important feature of the situation and an element in the clinical problem which should be combated by every means in one's power. Cardiac dyspnea is an exhausting and distressing experience but one which the physician rarely thinks much of treating until it is pronounced. It is as I have indicated, capable of adding to the fluid in the lungs and pleural sacs.

At the same time there is usually anoxia, which is so important for altering the permeability of the pulmonary capillaries toward increased leakage. This matter of anoxia as an element in the production of

Fig 4—Lymph flow as a result of breathing against inspiratory resistance. Upper curve (A.P.) indicates arterial pressure, middle curve (R.D.L.) lymph from the right lymphatic duct in milligrams per minute, lower curve (V.P.) negative pressure in the chest. Lymph flow became 11 mg a minute after an hour and a half of unresisted breathing. When inspiration was impeded by cotton wool resistance lymph flow rose to 82.5 mg a minute. On removal of resistance flow fell but again increased when resistance was reimposed and 10 per cent carbon dioxide was added to the oxygen in order to force maximal inspiratory effort. (From Warren, Peterson and Drinker³)

pulmonary edema has been easy to explore experimentally. The chest of a dog is opened by removing the upper part of the sternum down to the third ribs which are cut. This exposure brings the base of the

⁴ Yamada, So Sabro and assistants. Leber die seröse Flüssigkeit in der Pleurahöhle der gesunden Menschen. *Ztschr f. d. exper. Med.* 30: 342, 1933.

heart into view and the top of the upper lobes of the lungs. It is not a radical opening of the chest and leaves the lungs well covered and the heart undisturbed. Under these circumstances, which require artificial respiration, one may collect lymph during ventilation with pure oxygen and then shift suddenly to ventilation

Fig. 5—The flow of lymph from the lungs when alveolar oxygen is lowered. Dots with figures, cardiac output in liters per minute, upper curve shows arterial blood pressure, second curve protein in lung lymph in percentage, third curve protein in lymph from the lungs in milligrams per minute, fourth curve milligrams of lymph from the lungs per minute. Between the vertical lines the animal received gas mixtures as shown, the rate and stroke of the respiration pump being always uniform. (From Warren, Peterson and Drinker²)

with oxygen poor mixtures. In order to prevent any tendency to respiratory movements during periods of oxygen lack the animals may be curarized in addition to the complete soluble barbital anesthesia. The results are shown typically in figure 5. In this instance ventilation of the animal with air was first instituted. In this experiment lymph flow from the lungs became steady at 97 mg a minute. Under these circumstances the oxygen content of the blood was 16.08 volumes per cent and the cardiac output 2.13 liters a minute. With the same rate and stroke of the respiration pump the ventilation was then changed to 13.5 per cent oxygen and 86.5 per cent nitrogen. Cardiac output fell to 1.92 liters a minute and the oxygen saturation of the arterial blood became 9.48 volumes per cent. This change did not increase lymph flow or alter lymph protein concentration. When, however, ventilation was made 10 per cent oxygen and 90 per cent nitrogen, lymph flow rose at once. Cardiac output fell to 0.95 liter a minute and the oxygen saturation of the arterial blood became 4.23 volumes per cent. This very low figure could not be endured long. The interesting point is not that the capillaries of the lungs leaked considerably under these conditions but that, just as soon as ventilation was shifted back to room air, lymph flow fell at once to the figure which existed before the reduction in oxygen began.

This is an important and sensitive indication of the way in which very acute oxygen lack causes increased free fluid in the lungs. It should be noticed too how quickly adequate oxygen in the ventilating air stopped a pernicious process. When oxygen lack causes the pulmonary capillaries to begin to leak, the very fact of increased fluid in the lung tissues, and even more in the alveoli, cuts down the ease of passage of oxygen into the blood capillaries.

The clinical implications of these findings are sufficiently obvious. The capillaries of the lungs are in a unique position. They gain then oxygen from the air not secondarily from the blood. From what I have had an opportunity to see experimentally, I believe that clinically we fail to appreciate the patient's need for oxygen until too much time has passed. If you decide that a man needs oxygen, it is my belief that you are usually about twelve hours late. The time to use oxygen in treatment is before you think it is necessary. Such a course of action is expensive and formidable but if you wait until leakage from the pulmonary vessels is pronounced it will be difficult to check the cycle that has begun. It is better, then, to waste oxygen than to risk the circumstances which may attend delay.

EXUDATES

So much for an inadequate view of the formation of transudates. If irritation by chemicals, viruses or bacteria causes exudation from the pulmonary capillaries the results for the patient are usually worse than when transudation occurs. The entrance of air into the alveoli is blocked by coagulated exudate and cells in the finer bronchi and alveoli. The pulmonary lymphatics in their turn may readily be plugged by thrombi, and the situation makes for maximal difficulty in lung function. Not only is the lung flooded by exudate but fibrin formation interferes with removal of the exudate. When clotting occurs in and about an area of inflammation healing takes place either wholly or partially by scar formation. This may do relatively little harm in many parts of the body, but in the lungs there is inevitable loss of function.

Solution of the exudate and removal of small molecules through vascular absorption is the most efficient and rapid means of clearing the lungs of exudates. If the irritant does not destroy cells extensively coagulation of the exudate may be slight, and in this case it

Fig. 6—The flow and composition of lymph from the lungs in a dog given 45 parts per million of chlorine for thirty minutes three hours prior to the beginning of the record. The initial increase in lymph flow is due to obstruction and manipulation during the operation. The real change due to chlorine began eight hours after administration of the gas. Upper curve (A.P.), indicates arterial blood pressure, second curve (O₂) oxygen in arterial blood, third curve (P), lymph protein in percentage, fourth curve (L.L.), lymph flow in milligrams per minute.

will drain steadily through the lymphatics. In all parts of the body the lymphatics carry away substances from the tissues which as such are not absorbable by the blood capillaries. Most notable of these are the blood

proteins, which leak in slight amounts from the capillaries practically all over the body, exceptions being found in the renal glomeruli, the choroid plexuses and the capillaries of the ciliary body. From the lungs as has been shown in figures 2, 3, 4 and 5, lymph flows continuously. It contains 2 to 3.75 per cent of blood proteins and clots, but clotting does not occur in the lung tissue or lymphatics unless irritation has been severe enough to kill cells and release thromboplastic material.

As in the case of lymph movement all over the body, motion of the lungs is extremely important for causing lymph flow. A quiescent lung produces almost no lymph from large collecting trunks and what little can be garnered is due to the pulsation of the pulmonary vessels.

The lungs are peculiarly adapted to absorb water by virtue of their vast capillary bed. Colin⁵ in 1873 gave 21 liters of water to a horse intratracheally in three and one-half hours without the slightest detriment to the animal. When one considers the low hydrostatic pressure in the pulmonary capillaries and the comparatively high colloid osmotic pressure of the blood proteins it is not surprising that this is the case. The lungs are thus beautifully organized to rid themselves of excess water unless as is particularly apt to occur in young patients with mitral stenosis and with an abnormal resistance to flow of blood through the lungs transudates are formed and, as a result of the increased pressure in the alveolar capillaries, water cannot be absorbed.

If the lungs of a healthy anesthetized dog are irritated with chlorine in an amount which would be fatal if the animal was permitted to recover from the anesthetic, a curious series of events ensues. Using 45 parts per million of chlorine for half an hour one notices no change in lymph flow or composition for about eight hours (fig. 6). In this experiment the chest of the animal is opened and ventilation by air is provided by a pump which operates uniformly. The result is a very vivid expression of the way in which certain lung irritants act. Examinations of patients and trials on animals have shown that after a number of sorts of gassing there is a period of varying length in which the victim is quite normal. This does not take place if the gas is too concentrated, but in the case of common offenders—nitrogen dioxide, chlorine and phosgene—the individual may have breathed a fatal dose of the gas but his dangerous symptoms do not appear for some time.

The dog in this experiment drowned in a pulmonary exudate which did not begin to accumulate significantly until eight hours after the gassing. This exudate eventually clotted owing to cell damage as one can readily see in sections of the lung. Coagulation not only fixed fluid in the alveoli and bronchi but clogged the lymphatics so that from every angle the animal was totally assailed.

How can such conditions be treated? It is an interesting fact that blood continues to pass through the lungs even under the worst situations. That is even though the lung capillaries are caused to leak freely they do not fail to conduct blood. What fails is oxygenation of the blood. You can assist this by giving pure oxygen to breathe instead of air and even more so by placing

such patients in pure oxygen under one or two atmospheres of pressure. Perhaps other therapy may help, but essentially these patients need oxygen, for the changes which have been caused by the irritant gas produce oxygen lack in a steadily mounting form. This is the essential physiologic problem and the only way to combat it is by the early use of pure oxygen and even by the use of oxygen under pressure. There is no efficient way of getting oxygen into the body except through the lungs, and if the barrier between alveoli and blood has become abnormal the pressure of the oxygen in the lung air must be increased so as to force it in.

CONCLUSION

I should like to point out that, though I have spoken quite positively, my remarks have dealt mainly with experiments. Consider them as yeast which may rise as ideas in your minds and lead to facts.

Dr Folin, the greatly distinguished and intrepid biochemist at Harvard, believed that scientific advance arose through the devising of new methods. In many respects he was right but method as Pasteur expressed it save that he used the word "chance" awaits "the prepared mind." The difficulty with experimental advance resides in finding the combination of the "prepared mind" and the technical skill necessary for the experiment. In the issues I have pictured, it is certain that direct experiments may be done. There can be no doubt that the pulmonary lymph reflects rapidly in the living animal changes which will be fatal if they are not resisted. It is a continuous expression of change in the lungs as against the deductions which may be drawn from the sacrificed or dead animal. Equally true is the fact that different measures for combating pulmonary edema and pulmonary exudates may be examined in progressive physiologic experiments such as I have described and do not require the depressing finalities of the autopsy table to give one a poor idea of the way to combat a familiar clinical entity.

This is the message I wish to leave with you. Well conceived and adroitly accomplished mammalian experiments may mean much to human therapeutics. But make no mistake, experiments on mammals are supremely difficult. Very often the experimenter sees surprising and arresting things but ever and always he should ask himself whether what he has observed is the way in which the animal has reacted against the technical mistreatment of the experiment or whether it is a significant truth the results of which may be applied to the diagnosis and treatment of disease.

55 Shattuck Street

Treatment of Gas Gangrene—Once gas gangrene is established the most drastic treatment must be employed. The general principles are the same as those on which prophylaxis is based: radical excision of all damaged muscular, cellular, integumentary and other tissues. Owing to the spread of the infection in a longitudinal upward direction and its rapid passage from the initial focus through the whole muscle and then to the adjoining muscles, gangrene sometimes spreads from the thigh to the trunk in less than twenty-four hours. It is therefore vital that treatment should be carried out before the infection has passed beyond its localized stage. Four weapons are available against an established infection: surgical operation, antiserum, chemotherapy and deep x-ray therapy.—Trauma to Ceph. The Principles and Practice of War Surgery. St. Louis: C. V. Mosby Company, 1943.

TRICHINOSIS AND PERIARTERITIS
NODOSA

DIFFERENTIAL DIAGNOSIS, POSSIBLE RELATIONSHIP

HOBART A. REIMANN, M.D.

ALISON H. PRICE, M.D.

AND

PETER A. HERBERT, M.D.

PHILADELPHIA

Although differential diagnostic difficulties seldom arise in cases of "typical" acute trichinosis, the problem is not so simple in mild, subacute, chronic or otherwise unusual ones, which comprise the majority of cases.¹ Hall² lists about fifty diseases or conditions which have been mistaken for trichinosis, yet neither he nor most authors include periarteritis nodosa as one of them in spite of its clinical resemblance to trichinosis. On the other hand, trichinosis is often mentioned in discussions of the differential diagnosis of periarteritis nodosa. In fact, numbers of cases of periarteritis nodosa have been recognized by the typical histologic lesion at biopsy in cases of suspected trichinosis. In diseases as similar to each other and as variable in their manifestations as trichinosis and periarteritis nodosa, it is surprising that no mention is made in any of the reports we have read of serious problems in differentiating them. Differentiation seems to resolve when clearcut evidence eventually develops in one direction or the other. However, since about 16 per cent of the general population has asymptomatic trichinosis,³ the possibility or likelihood of the two diseases occurring in the same patient must be considered. It is even possible that one may cause the other. Early diagnosis is important because of the difference in the two diseases of prognosis and of epidemiologic management.

Problems in diagnosis which may arise in trichinosis or periarteritis nodosa and evidence of the possible relationship of the two diseases are illustrated in the following reports.

REPORT OF CASES

CASE 1—History—C. P., a laborer aged 35, had had asthmatic attacks since November 1939, which gradually became worse but never interfered with his work. In December 1940 he "caught a cold," which obliged him to go to a hospital for several days for severe asthma. A brief attack of watery, bloody diarrhea occurred. He recovered, but early in February 1941 severe coughing, dyspnea, occasional hemoptysis and anorexia developed. On February 14 "intestinal grip" with watery, bloody diarrhea recurred and lasted several days. Pain developed in his calves, ankles and feet, with tingling and numbness. During this time there were chilliness, night sweats, vomiting, diarrhea, paroxysms of coughing and lacrimation with pain and burning. He was admitted to the hospital six days later complaining of chilliness, night sweats, anorexia and weakness. He had lost 11.3 Kg (25 pounds) in two months.

On admission to the hospital the patient was seriously sick, was pallid and had a temperature of about 38.9 C (102 F). There were conjunctivitis, edema of the lids and periorbital

tissues, and a flame shaped hemorrhagic area in the left retina. The heart and the lungs, except for sibilant "asthmatic" rales in an emphysematous chest, were apparently normal. The liver and spleen were palpable. Lymph nodes in the epitrochlear region were slightly enlarged and one was excised for study. The calves and ankles were painful on movement and tender to pressure but otherwise appeared to be normal. The patellar reflexes were hyperactive. The blood pressure was 130 systolic and 70 diastolic.

The hemoglobin and erythrocytes were normal in amount. The leukocytes numbered 11,000, of which 30 per cent were eosinophils. The sedimentation rate of erythrocytes was increased, with almost complete settling in twenty minutes. A small amount of blood flecked sputum was raised during asthmatic attacks in which eosinophils comprised 28 per cent of the leukocytes present. Jaundice was not revealed by the van den Bergh test, and the spinal fluid was normal. Urinalysis showed 2 plus albumin and granular casts, the blood urea nitrogen measured 9.5 mg per hundred cubic centimeters and the urea clearance was 166 per cent of normal. Serologic tests for syphilis gave negative results. The stool contained occult blood but no parasites. Evidence of emphysema, acute tracheobronchitis and possibly pneumonia was seen in a roentgenogram, but the heart was normal in size. An electrocar-

digram showed no abnormality. In tests for hypersensitivity the patient's skin reacted positively to wheat, ragweed pollen and plantain pollen and was weakly positive to feathers and house dust.

Because of the onset with diarrhea, periorbital edema, conjunctivitis, a retinal hemorrhage, pain and tenderness in the calves and eosinophilia, a tentative diagnosis of acute trichinosis was made. The patient on questioning said that for months he had regularly eaten hurriedly cooked hamburger or pork sausage sandwiches and other meats in quick lunch places. Splenomegaly could not then be accounted for, asthma and nephritis were thought to be unrelated conditions.

Course of the Disease—An irregular temperature, reaching 38.3 C (101 F) on occasion, persisted for over five months, after which it was lower but still touched 37.8 C (100 F) in July. Bloody diarrhea recurred for several days in February, transient lymphadenopathy occurred in the left axilla and at intervals severe asthmatic attacks. The general condition became worse until April, when gradual improvement began despite evidence of progressive renal failure. The urea clearance diminished from normal to 58 per cent in five months. There were persistent 2 plus to 3 plus albuminuria, granular casts and occasional erythrocytes in the urine. The leukocytes were always increased in number, often as high as 20,000. Eosinophilia ranged from 12 to 46 per cent. The pains and

numbness in his legs decreased but the patellar and achilles reflexes disappeared. Bilateral foot drop and slight atrophy of the quadriceps muscles resulted from what probably was peripheral neuritis. Anemia with 60 per cent hemoglobin and 3,000,000 erythrocytes was present. He returned to his home in July 1941.

Fig 2—Occlusion of a vessel in striated muscle by extensive intimal proliferation. There is panarteritis and periarteritis. The intima contains a giant cell. Hematoxylin and eosin X 200.

He was fairly well until January 1942, when sudden severe dyspnea forced him to return to the hospital. The temperature rose to 38.9 C. (102 F) and returned to normal in a week. The leukocytes numbered 27,000, 11 per cent were eosinophils. During this time the asthmatic attacks and cyanosis were most severe, requiring epinephrine and oxygen for control. He improved and was discharged.

Reexaminations were made in February and October 1942. During the spring and summer he improved and returned to work. He was weak, tired easily and had dyspnea on exertion and occasional pains in the wrists or ankles. The blood pressure

Fig 3—Hyalinization of some muscle fibers ballooning and cystlike formation in others. The infiltrating cells are plasma cells, lymphocytes and polymorphonuclear leukocytes. Hematoxylin and eosin X 200.

gradually rose to 170 systolic and 115 diastolic. He had no asthma until August but had to stop working in October because of the severity of the attacks. The attacks were relieved with ephedrine or epinephrine. By this time the evidence of renal and cardiac failure had become pronounced. There were pretibial edema, pulmonary congestion, hepatomegaly, spleno-

megaly, leukocytosis, eosinophilia, albuminuria and persistent hypertension. The urea clearance was 30 per cent of normal. An electrocardiogram showed a normal tracing. Biopsy of the pectoralis major and gastrocnemius muscles was made.

The patient's condition in April 1943 remained about the same.

Biopsy Reports—In the lymph node removed at biopsy in March 1941 there were areas of inflammation about most of the blood vessels, particularly at their bifurcation. The intima and media of many of the arteries showed fibrinoid necrosis so severe in places as to occlude them with debris (fig 1). The vessel walls were diffusely invaded by polymorphonuclear leukocytes, plasma cells, eosinophils, lymphocytes and erythrocytes. The periarteritis, polyarteritis and panarteritis strongly suggested periarteritis nodosa. In the parenchyma of the lymph node the follicles were almost entirely displaced with cells of the same kind.

In a section of muscle excised from the gastrocnemius at the same time the blood vessels were involved by a similar but more severe process. The entire arterial wall was invaded and the lumen was almost occluded by proliferation of the intima (fig 2). Occasional nuclei in the intima were heaped together to form giant cells. The perivascular inflammation extended for varying distances into the surrounding connective tissue. In addition there were areas of focal myositis in no apparent relation to vessels which showed extensive hyaline degeneration.

Fig 4—Vessel in striated muscle showing remnants of the media at the upper and lower poles. The entire wall particularly the intima is fibrotic. Capillaries have canalized the occluded lumen. The vessel wall and perivascular tissue are infiltrated with lymphocytes and plasma cells. Hematoxylin and eosin X 200.

of the fibers. In places, many of the fibers resembled thin pink shells of tissue or cysts distended with large plasma-like cells (fig 3). Similar cells together with polymorphonuclear leukocytes and erythrocytes infiltrated the adjoining fibers and connective tissue. The balloon-like areas resembled those which ordinarily enclose trichinella larvae, but no larvae were found and no eosinophils were present.

In a section of muscle removed several weeks later a number of vessels were extensively fibrotic, especially in the intima as healing was in progress (fig 4). Occluded lumens were canalized. Traces of inflammation remained as a few plasma cells, lymphocytes and pigmentary remains of previous extravasations of erythrocytes. Ten months later arteritis had disappeared, leaving fibrous thickening of many vessels. There were extensive fibrosis, scattered leukocytes and free and phagocytosed pigment in the perivascular tissue. In sections from the pectoralis major and gastrocnemius muscle made twenty months later in November 1942 all abnormalities vascular or otherwise had vanished except for a few lymphocytes and plasma cells about an occasional vessel.

Specific Tests—A specimen of blood serum examined in February 1941 by Dr Sandground of the Lill Research Laboratories gave a positive precipitin test with trichinella antigen in a titer of 1:800. A second specimen tested by Dr

Wright of the National Institute of Health was positive in a titer of 1:640. Intracutaneous tests made on several occasions with different antigens supplied by Dr. Sandground and Dr. Wright were negative, as was a complement fixation test. A precipitin test performed by Dr. Wright eleven months later, in January 1942, was positive in a dilution of 1:1,280, but a test in our laboratory in February 1942 was negative. In October 1942 both precipitin and complement fixation tests (Dr. Wright) were negative. A cutaneous test gave rise to an erythematous area 5 mm in diameter at twenty-four hours.

As stated previously, trichinosis was strongly suspected because the patient ate poorly cooked pork for months. The illness apparently began acutely with bloody diarrhea and fever, followed by pains in his calf muscles, periorbital edema, leukocytosis and eosinophilia. The microscopic evidence was suggestive and precipitin tests with trichinella antigen were positive in high dilution. Only the absence of trichinellae in the muscles, the negative cutaneous tests and complement fixation reaction weakened the diagnosis. Such discrepancies, however, are common in trichinosis. Restudy of muscle tissue, on the other hand, strongly suggested periarthritis nodosa. Nevertheless trichinosis, being the more common disease, was still favored, since even though trichinellae were not seen in the muscle

Fig. 5—A vessel in striated muscle seen in figure 6. The intima and inner media show massive fibrinoid necrosis with almost complete occlusion of the lumen. The diffuse inflammatory reaction consists chiefly of eosinophils and polymorphonuclear leukocytes. Hematoxylin and eosin $\times 200$.

inflammatory changes such as were present may occur in adjoining muscle fibers and connective tissue⁴ and thrombophlebitis⁵ has been recorded.

As the disease progressed over many months the points in favor of a diagnosis of periarthritis nodosa seemed to gain weight, particularly the history of asthma commencing at the age of 33 and persisting, the prolonged, irregular, relapsing fever, lymphadenopathy, splenomegaly, eosinophilia, nephritis, neuritis and the periarthritis, polyarteritis and panarteritis. Yet prolonged fever, pseudoparalysis, splenomegaly, asthma, albuminuria and cylindruria may occur in the course of

trichinosis.⁶ Asthma, however, antedated the disease described by many months. The pain in the legs tingling, numbness and foot drop seemed more likely to be the result of neuritis, not myositis. The periorbital edema may have been related to nephritis.

Study of the patient in October 1942, nearly two years after the onset of illness, revealed no clinical, microscopic or serologic evidence of either disease but only a progression of the nephritis and cardiac failure, which are common terminal events of periarthritis nodosa.

Several possibilities may be suggested to account for the patient's illness: (1) periarthritis nodosa, of which the acute stage had passed, leaving lesions which healed or disappeared with the exception of the renal ones, which are progressive, (2) repeated infections with *Trichinella* or chronic trichinosis with unusual manifestations, since the precipitin test is supposedly reliable as a confirmatory test⁷ and negative cutaneous tests usually thought to be more reliable, do not necessarily exclude the diagnosis, (3) both trichinosis and periarthritis nodosa in the same patient, either one preceding the other, or (4) an underlying allergic condition, which may be regarded as definite, since many members of the patient's family had "allergic" diseases and the patient had asthma. It is possible that trichinosis, which is also characterized by allergic manifestations, may have aggravated the existing condition or even caused it and brought about the microscopic reaction and subsequent disease regarded as periarthritis nodosa.

Case 2—History—P. C., a man aged 38, a Korean born in the Orient, was admitted to the hospital in November 1941 complaining of pain in the calves and shoulders, weakness and loss of weight. In August pain in the neck, shoulders and lumbar and sacral regions lasted for several days in each area and disappeared in about four weeks. Pain then developed in one and then in the other knee, which became red, hot and swollen. This subsided in two weeks, to be followed by arthritis of both ankles, enforcing rest in bed. Soon the muscles of both calves became tender and painful, which made walking impossible for a time and overshadowed other pains and aches. There was also pain in both masseter muscles. These pains lasted about six weeks and gradually subsided. There was residual stiffness of the shoulders and legs, particularly in the morning. There had been occasional night sweats for five weeks and loss of 7.2 Kg (16 pounds). Obstinate constipation developed.

During the early part of the summer the patient did not feel well and was said to have had anemia, for which he ate large amounts of raw beef and raw pork. The patient, like many Koreans, had eaten poorly cooked meats most of his life. He had had sinusitis for twenty years.

On physical examination the patient was thin but in no apparent distress. The scleras and conjunctivas were inflamed and the lids were edematous. The ocular fundi were normal. There was severe chondritis of the auricle of the right ear and both drums were reddened. Thick pus containing *Staphylococcus albus* was present under the turbinate bones, and there was roentgenographic clouding of the frontal, ethmoid and maxillary sinuses. The heart and lungs were apparently normal. The spleen and liver were palpable.

The extremities, including the reflex reactions, were normal except for thinness and tenderness of both calves. There was tenderness and pain on motion of the shoulders and elbows.

The hemoglobin was 68 per cent, the red cells numbered 3,400,000 and the leukocytes 8,000, of which 68 per cent were polymorphonuclear cells, 26 per cent lymphocytes and 6 per cent

cosinophils. The sedimentation rate in December and in February was rapid with complete settling in thirty minutes. The Wassermann and Kahn reactions of the serum gave negative results. Urinalysis showed 2 plus albumin, no erythrocytes and a few granular casts. A blood culture was sterile.

Because of a history of having eaten raw pork, painful calf, masseter and other muscles, palpebral edema and eosinophilia,

Fig 6—A group of vessels diffusely infiltrated with inflammatory cells near their bifurcation in striated muscle. There is extensive fibrillation of the internal elastic membrane. Elastic tissue stain. X 40.

trichinosis seemed most likely as a diagnosis, but splenomegaly and evidence of nephritis, as in case 1, again raised the question of periarteritis nodosa. Chronic purulent sinusitis was obvious.

Course in the Hospital.—The patient was observed for five months. The temperature was irregular, reaching 38.3 C (101 F) occasionally for a month after which it subsided coincident with improvement of the sinusitis resulting from drainage and irrigation. It frequently reached 37.5 C (99.5 F) but became normal two weeks before he left the hospital. The conjunctivitis disappeared. Inflammation of the auricle of one ear gradually healed but later involved the other. The blood pressure was labile, ranging irregularly from 110 systolic and 60 diastolic to 170 systolic and 130 diastolic but was usually 130 systolic and 70 diastolic. The arthralgia and myalgia lessened considerably after a week or two, but the left wrist on one occasion became painful, tender, swollen and hot for several days.

In December a group of papules 3 to 5 mm in diameter appeared in a small area on the scrotum to which attention was attracted by itching. A portion was excised for biopsy. The blood count remained rather constant the proportion of eosinophil cells ranging from 1 to 18 per cent.

The urine throughout gave evidence of nephritis with persistent 2 plus to 3 plus albuminuria. A few leukocytes and granular casts were constantly present. The urea clearance at this time was 74 per cent of normal but progressively decreased to 14 per cent and 9 per cent in three months. The general condition, the myalgia, arthralgia and sinusitis improved so that the patient returned to his home in February, although he was weak and anemic in spite of hematonic treatment. He had regained 9 pounds (4.1 Kg).

He returned to the hospital after four weeks complaining chiefly of dyspnea, restlessness, insomnia and vomiting. There was general anasarca and purulent nasal discharge. Uremia was evident. The anemia had increased but no eosinophil cells were seen. The urea clearance test was 8 per cent of normal. The blood pressure was 190 systolic and 140 diastolic. He lapsed into coma and died after a convulsion on May 5. The clinical diagnosis was trichinosis, chronic glomerulonephritis, chronic sinusitis and uremia. The histologic diagnosis from biopsy was periarteritis nodosa.

Biopsy Reports.—In December tissue from the gastrocnemius muscle showed diffuse infiltration of the blood vessel walls and perivascular areas with eosinophils, polymorphonuclear leuko-

cytes and occasional plasma cells and lymphocytes. Most of the vessels were occluded by proliferation and fibrinoid necrosis of the intima and inner layers of the media (fig 5). Diffuse hemorrhagic extravasations but no aneurysmal dilatations were seen. As in case 1, the reaction was especially severe at the bifurcation of vessels. There was abundant fibroblastic proliferation in the perivascular connective tissue. Elastic tissue stain revealed extreme fibrillation of the internal elastic membrane (fig 6) and slight patchy hyalinization of the muscle fibers. There were no focal areas of myositis dissociated from the vessels and no trichinella larvae were found. The lesions were typical of those of periarteritis nodosa.

Tissue from the scrotal papule showed superficial ulceration of the epithelium. The underlying dermis was rich in engorged, thin walled capillaries, fibroblasts, eosinophils and occasional polymorphonuclear and plasma cells. Vessels not near the ulcers were unchanged. The nature of the lesion was essentially like that in the muscles.

Necropsy Report.—Six months later at necropsy careful search revealed no evidence whatever of either active lesions or healed scars of periarteritis nodosa in the heart, aorta, lungs, spleen, adrenal glands, liver, gallbladder, pancreas, gastrointestinal or urinary tract or vertebral bone marrow. Encysted trichinella larvae, however, were present in the pectoralis major muscle (fig 7). There was no inflammation or calcification about them and the arteries in the muscle appeared normal. The brain was normal except for evidence of toxic effects on the ganglions, and an occasional artery or vein was surrounded by a loose collection of small monocytes. The nasal sinuses contained no pus, but the lining membranes were thickened. The sphenoid sinus had ruptured into the pituitary fossa but the latter was not inflamed. Death was evidently caused by chronic glomerulonephritis with acute exacerbation. Glomerular lesions, tubules containing cellular casts and patchy infiltration of the interstitial tissue were present. The arteries, however, were remarkably free from inflammation and even from such sclerosis and fibrosis as are ordinarily present in chronic glomerulonephritis.

Specific Tests.—Because of the clinical impression of trichinosis, blood serum was sent to Dr. Wright for precipitin tests in December 1941. The test was positive in a dilution of 1:1,280. Blood taken in February 1942 was again sent to

Fig 7—Encysted *Trichinella spiralis* larva in pectoralis major muscle. Note the absence of inflammation and calcification. Hematoxylin and eosin. X 200.

Washington where the test was reported as negative but a sample of the same serum tested by Dr. Sandground was reported positive in a titer of 1:800. Cutaneous tests made on three occasions with intradermal injections of different antigens supplied by Dr. Sandground and by Dr. W. H. Wright in December, January and February 1942 all gave negative results. A complement fixation test performed with trichinella antigen also supplied by Dr. Sandground gave a negative result.

The diagnostic problem was similar to that in case 1. Although the so-called acute "primary" stage of trichinosis was not seen or recorded, the history of a lifelong custom of eating undercooked pork makes the infection with *Trichinella spiralis* very likely. The additional large amounts of deliberately eaten raw pork just before the onset of illness may have induced a reaction to which the patient reacted in a manner different from the so-called classic case. The painful shoulder and masseter muscles, the recurrent arthritis characteristic of a late stage of trichinosis called "trichinial rheumatism," prolonged fever, periorbital edema, conjunctivitis and eosinophilia all pointed to that diagnosis. As in case 1, the enlarged spleen and evidence of nephritis added a degree of diagnostic confusion which was heightened by the histologic changes of periarteritis nodosa in the muscle. Additional diagnostic factors in favor of periarteritis nodosa were the prolonged febrile period, arthritis and eventual death in uremia. Asthma never occurred. At the time it was thought that the spleen may have been enlarged from preceding forgotten or unrecognized disease during residence in Korea, and the chronic nephritis may have followed the chronic purulent sinusitis or may have been related to trichinosis. Again as in case 1 several precipitin tests for *Trichinella* were strongly positive, but all specific cutaneous tests and a complement fixation test were negative. The precipitin test on one occasion was reported as positive from one laboratory and negative from another.

Trichinellae were indeed found at necropsy, but no evidence, present or past, of periarteritis nodosa was found even in the kidneys, in which only the changes of commonplace chronic glomerulonephritis were present. The spleen, palpable during life, was normal in size and structure. The presence of *Trichinella* larvae in the muscles, of course, proved the diagnosis of trichinosis. But the typical microscopic lesions of periarteritis nodosa seen during life, with nephritis terminating in death, are unaccounted for except as (1) a possible result of chronic purulent sinusitis, (2) an unusual, hitherto undescribed reaction in trichinosis, (3) manifestations of periarteritis nodosa occurring as a separate disease during trichinosis, the evidence of which disappeared before death, or (4) trichinosis inciting the microscopic reaction and syndrome known as periarteritis nodosa.

COMMENT

It is obvious that during certain periods of either trichinosis and periarteritis nodosa the similarities between them may be so great as to make clinical diagnosis impossible without the demonstration of *Trichinella* in the 1 case or of widespread microscopic evidence of active, subsiding or healed lesions of periarteritis nodosa in the other. In certain cases, as in those described, when evidence of both conditions is present, the matter is indeed complex. In both cases described, the clinical diagnosis was trichinosis yet the microscopic diagnosis during life was periarteritis nodosa.

Albuminuria or renal failure in either patient could not be regarded as secondary to trichinosis of the myocardium and heart failure with no evidence therefor. Chronic nephritis more likely caused heart failure. Albuminuria and casts have been recorded in cases of trichinosis. Asthma, as case 1, is an especially common symptom in periarteritis nodosa, but it may also occur in trichinosis.

In both cases described the contradictory results of various specific tests for trichinosis are confusing. It

is generally believed that the cutaneous test is more reliable than the precipitin test, but even it may be misleading. Particularly confusing are the results in case 2, in which *Trichinella* was present in the muscles, yet the cutaneous test, the complement fixation test and on one occasion the precipitin test gave negative results.

Recovery from trichinosis is the rule, but periarteritis nodosa is supposedly a fatal disease. There is, however, reason to believe that healing and recovery may occur at times if the damage done is not too great. Recovery probably happens more often than is realized, but the disease may be unrecognized unless a biopsy is made. According to studies at necropsy, patients have recovered from the acute stage of periarteritis nodosa but died from nephritis or heart failure, and remnants or scars of extensive vascular disease or healed infarcts in various organs have been described.⁸ In case 1 nephritis exists but arteritis, present early in the disease, vanished except for a few traces after twenty months. In case 2 death was caused by nephritis, but arteritis was not found at necropsy.

POSSIBLE RELATIONSHIP OF TRICHINOSIS AND PERIARTERITIS NODOSA

With asymptomatic trichinosis present in an estimated 16 per cent of the population³ there is reason to expect periarteritis nodosa as a separate, unrelated disease in an occasional infected person.^{8a} A patient with periarteritis nodosa may likewise contract trichinosis. Yet in both cases described here evidence of a causal relation of trichinosis to periarteritis nodosa is persuasive. In case 1, regarded clinically as one of trichinosis, microscopic changes suggested a progression of lesions, first of trichinosis, later of periarteritis nodosa and then of healing and final disappearance. In case 2, unquestionably one of trichinosis, lesions of periarteritis nodosa were present during life but no remains of them were found at necropsy. Progressive renal failure occurred in both. It is probable that in both trichinosis was the primary factor which initiated the vascular lesions and the clinical syndrome known as periarteritis nodosa, probably through the obscure mechanism of allergy, and that the progressive renal impairment was the result of the vascular injury. Certain cases of chronic nephritis of obscure origin may also be explained on this basis. According to experimental studies trichina antigen is excreted in the urine for weeks after infection of monkeys.^{8b} Chronic trichinosis or repeated reinfections give a prolonged opportunity for the development of antibody and its interaction with the antigen.

The possibility that *Trichinella spiralis* or other nematodes may serve as one of the causes of, or may initiate the onset of, periarteritis nodosa was suggested twenty-five years ago,⁹ but in no other report of the latter have we found mention of evidence of trichinosis.

in studies of tissue. Nevertheless, various allergic manifestations such as asthma, urticaria edema and eosinophilia common to the two diseases lends credence to the theory.

Periarteritis nodosa is apparently a syndrome of diverse origin. The possibility that it may be a result of hypersensitivity was suggested by Gruber¹⁰ in 1925 and discussed in a recent review by Rich.¹¹ Rich refers to previous observers who described periarteritis nodosa in patients with serum sickness and adds 5 cases of his own. In further studies he¹² induced the typical lesions of periarteritis nodosa in rabbits by injecting them with horse serum.

CONCLUSION

The 2 cases presented were regarded clinically as trichinosis, yet the typical lesions of periarteritis nodosa were present in tissue examined during life. Both patients had chronic nephritis. One died, and at necropsy no evidence of periarteritis nodosa remained, but trichinellae were found in the muscles. There is a possibility that trichinosis as a disease with strong allergic manifestations may in certain instances serve as one cause of the syndrome called periarteritis nodosa.

LIVER FUNCTION TESTS IN CLINICAL MEDICINE

FREDERICK STEIGMANN, M.D.

HANS POPPER, M.D.

AND

KARL A. MEYER, M.D.

CHICAGO

Knowledge of the functional status of the liver, gained by the use of tests, is growing in importance in medicine and surgery. Such tests are particularly helpful (1) in patients with jaundice and (2) in some without jaundice as in (a) cirrhosis of the liver, (b) gallbladder disease, (c) controlling the therapy with hepatotoxic drugs and (d) hyperthyroidism.

Our object is to give the indications and uses of liver function tests based on our experience gained from examination and study of 563 jaundiced and 112 non-jaundiced patients. In 111 of these cases which came to operation our studies were supplemented by histologic and fluorescence microscopic examination of liver biopsy specimens.

WHICH LIVER FUNCTION TESTS ARE USEFUL?

The answer to the question Which liver function tests are useful? depends first on whether or not the patient is jaundiced.

1. In jaundice, the usual problem is to decide whether it is obstructive or parenchymatous and whether surgical intervention is indicated. Some liver damage occurs in almost every case of jaundice. In paren-

chymatous jaundice it is usually acknowledged, however, even in obstructive jaundice regurgitated bile may cause liver damage. In the differentiation between obstructive and parenchymatous jaundice, less sensitive liver function tests are indicated—tests which give positive results only if more severe damage to the liver parenchyma is present. In cases of mild hepatitis in which such liver function tests may be negative, the question of surgical intervention usually does not arise.

2. In patients without jaundice, on the other hand, one is often interested in discovering slight deviations of liver function. For such patients the more sensitive liver function tests are needed.

WHAT MAY BE LEARNED FROM LIVER FUNCTION TESTS IN JAUNDICE?

A Differentiation Between Medical and Surgical Jaundice Within the First Six Weeks—After this period, secondary liver damage due to prolonged obstruction becomes severe enough to produce the same functional changes as in cases of severe primary hepatitis. If, however, after six weeks of jaundice the less sensitive liver function tests still yield negative results, they may be of diagnostic value.

B Indications for Immediate Surgical Intervention in Patients with Obstructive Jaundice—If during the observation or preparation period of a patient with established biliary obstruction liver function suddenly fails, immediate surgical relief of the obstruction is indicated.

C Estimation of the Degree of Liver Damage (or Liver Reserve), Especially in Chronic Liver Disease (as in Cirrhosis)—The knowledge of the degree of liver damage is important in the evaluation of the therapy.

D Prognosis in Acute Hepatitis—The course of the disease can be recognized by impairment (danger of acute yellow atrophy) or by improvement of the liver function. The results of liver function tests often indicate improvement before the jaundice has subsided.

WHICH PROCEDURES DIFFERENTIATE BETWEEN MEDICAL AND SURGICAL JAUNDICE?

Because of the inherent difficulties in liver function tests (presence of secondary hepatitis), attention should be given to examination of bile pigment metabolism before function tests of the type of the tolerance tests are used.

Bile Pigment Metabolism—The endothelial and especially the reticuloendothelial cells of the body form hemobilirubin from hemoglobin. This pigment is probably connected with plasma protein and circulates in the blood but does not pass into the urine. It gives the characteristic diazo reaction (van den Bergh) only after the serum protein has been precipitated with alcohol. Hemobilirubin is taken up by the liver cells and excreted into the bile capillaries as cholobilirubin which supposedly is freed of the protein connection. In the intestine, cholobilirubin is reduced by bacterial action to urobilinogen (stercobilirubin). Most of the stercobilirubin is excreted with the feces to which it imparts color, and part of it is reabsorbed into the blood stream and reaches the liver. The liver reoxidizes most of it to bilirubin which is again excreted in the bile (entero-hepatic circulation). Traces of it remain in the blood and appear in the urine (fig. 11). Normally, traces of urobilinogen and no bilirubin are excreted in the urine.

cholesterol-cephalin emulsion in various degrees, (b) the colloidal gold test in which pathologic globulins precipitate and change characteristically the color of gold chloride, (c) Takata-Ara test in which pathologic globulins flocculate an alkaline sublimate solution in serial dilutions.

The early globulin changes in acute hepatitis can be elicited by the cephalin-cholesterol flocculation test and by the colloidal gold test. The Takata-Ara test becomes positive only in chronic liver disease.

The technique of the cephalin flocculation test is described by Hanger.⁴ At present the cephalin-cholesterol mixture is available commercially. The test is simple and seems to have particular merits in the presence of jaundice. Because of the danger of false positives only dense flocculations are significant.

Blood Phosphatase Test—Physiology. Alkaline phosphatase is an enzyme which splits organic phosphorus compounds in an alkaline medium to inorganic phosphates. It is produced by osteoblasts and consequently it is increased in bone diseases. It is probably excreted through the bile and hence increases in the blood in disturbances of biliary excretion, as seen in extrahepatic obstruction or intrahepatic block or parenchymatous jaundice.

The technique is described by Bodansky.⁵ This test is often used in association with the cephalin-cholesterol flocculation test as they complement each other. A

Fig. 5—Schematic drawing explaining the results of the galactose and hippuric acid tests.

high blood phosphatase level with a high degree of flocculation speaks for hepatitis, while with a low degree of flocculation an uncomplicated extrahepatic obstruction is probable. By itself, however, the phosphatase determination is not of much diagnostic aid, since it possibly indicates only the degree of biliary obstruction which can be recognized much more simply by the urobilinogen excretion in the urine.

Duodenal Drainage—By this procedure—which is now much less used than it was previously—one can first note the presence or absence of bile from the duodenum by the color of the duodenal contents. If bile is present, liver bile and the darker gallbladder bile (obtained after duodenal instillation of 30 cc of a 40 per cent solution of magnesium sulfate) may be obtained separately.

Microscopic examination of the sediment shows many pus cells in the liver bile in cases

of cholangitis and in the gallbladder bile in cases of suppurative cholecystitis (empyema). Cholesterol, calcium carbonate and bilirubin crystals particularly in the gallbladder bile, speak for cholelithiasis. In

addition, the excretory function of the liver for dyes can be tested during the duodenal drainage by injecting azorubin S.

Technic for Azorubin-S Test⁶—Four cc of a 1 per cent solution of azorubin-S is injected intravenously and 20 cc of a 40 per cent solution of magnesium sulfate

Fig. 6—Schematic drawing of the relation of the albumin and globulin in the blood serum in normal and pathologic conditions (cirrhosis, nephrosis).

is instilled into the duodenum. Normally a red coloration of the bile appears within twenty-five to thirty minutes. In liver damage the excretion of the dye is delayed or not excreted at all.

The Colloidal Gold Test—Physiology. This is discussed under cephalin-cholesterol flocculation tests.

Technic—This is described by Gray.⁷ The test seems promising but is somewhat difficult to perform.

Comment—The application of the liver function tests mentioned raised the percentage of correct diagnoses—as checked by follow-up study, operation or postmortem examination—from 79 to 95 per cent. This indicates that the usefulness of the liver function tests is not as wide as is often assumed. It should be stressed that, despite a rather intensive clinical and laboratory work-up, the right diagnosis was not made in 5 per cent of the cases. During the five years of this study various improvements of the liver function tests were made and their number was increased. Nevertheless, the percentage of failures remained about the same throughout the years.

In analyzing these cases it was found that the chief cause for the failure was that patients with obstructive jaundice first came under observation at a time when secondary hepatitis had already developed. Obviously, impairment of liver function in cases of secondary hepatitis is identical with that in cases of primary hepatitis. Therefore improvement in the liver function tests alone will not decrease the percentage of failures in the differentiation between medical and surgical jaundice. An improvement can be expected only from more accurate clinical observation and care in taking the history. Any improvement of liver function tests would seem to lie mainly in the development of technically simpler procedures.

WHAT CRITERIA POINT TO IMMEDIATE SURGERY IN CASES OF OBSTRUCTIVE JAUNDICE BECAUSE OF IMMINENT LIVER BREAKDOWN?

1 Increase of the Icteric Index—Physiology. In obstructive jaundice, the urinary excretion of bilirubin removes relatively much of the regurgitated bilirubin. Thus after a while a fairly constant bilirubinemia results at an icteric index of 100 to 150. In parenchymatous jaundice, the associated kidney damage reduces the urinary excretion of bilirubin with consequently higher and rising icteric indexes.

⁶ Gray, S. J. *Colloidal Gold Reaction of Blood Serum in Diseases of the Liver*, *Arch. Int. Med.* 65: 523-544 (March) 1940.

The sudden rise of the icteric index from a fairly constant level points to a secondary parenchymatous complication

2 Falling Prothrombin Level During Administration of Vitamin K—Physiology In jaundice, the intestinal absorption of vitamin K is interfered with owing to the lack of bile acids in the intestine. In liver damage the storage of vitamin K in the liver is additionally impaired. Both factors cause prothrombin deficiency, which may be corrected by administration of vitamin K. In liver damage, however, the formation of prothrombin, even in the presence of vitamin K, is not normal. Therefore, after administering vitamin K to a jaundiced patient the consequent rise of the prothrombin level is prompt and prolonged if the liver is undamaged, whereas in cases of liver damage the rise is only slight and is not sustained.

Technic The determination of the prothrombin level may be done by the method of Quick⁸ and his co-workers or of Smith and his co-workers.⁹

If in a jaundiced patient under observation either the prothrombin level falls or, even worse, hemorrhagic diathesis appears, severe secondary liver damage has developed. That is confirmed by inadequate response to further vitamin K therapy.

3 Increase of the Nonprotein Nitrogen in the Blood—Physiology The nonprotein nitrogen level of the blood rises in parenchymatous liver damage partly because of increased protein breakdown and more so because of associated pathologic changes in the kidney. The latter is probably on the basis of an inability of the damaged tubular cells to prevent urea reabsorption.¹⁰

A sudden rise of the nonprotein nitrogen in a patient with jaundice is, therefore, an alarm signal.

4 Increased Alimentary Galactosuria or Decreased Excretion of Hippuric Acid—If, on repetition of these liver function tests, the previously normal results have turned pathologic, the development of a secondary hepatitis is indicated.

5 Millon's Test—Physiology In severe liver damage increased amounts of amino acids may be present in the blood and thus tyrosine appears in the urine, which is recognized by Millon's reaction.

Technic Add an equal amount of Millon's reagent¹¹ to urine and boil. A precipitation develops. A red color of the supernatant fluid indicates the presence of tyrosine. In case of albuminuria, the protein should first be removed from the urine in order to avoid the splitting off of tyrosine from the protein molecule.

WHAT DETERMINES THE DEGREE OF LIVER DAMAGE IN PATIENTS WITH JAUNDICE?

The tests presented here are those in which a somewhat quantitative relation exists between the results of the tests and the degree of liver damage. These relations are especially important in the follow-up of cases of chronic disease and in the evaluation of therapeutic procedures.

1 Hippuric Acid Excretion Test—The amount of hippuric acid excreted is to a certain extent inversely proportional to the degree of liver damage.

2 Cholesterol-Cholesterol Ester Ratio—Physiology Cholesterol is excreted with the bile, consequently in biliary obstruction the total cholesterol of the blood rises. Supposedly only the liver cells are able to esterify free cholesterol into cholesterol esters. In the presence of a normal liver, two thirds of the total cholesterol in the blood is in ester form (cholesterol-cholesterol ester ratio 1:2). In liver damage the esterification is impaired and consequently independent of the height of the total cholesterol, the ratio is changed to 1:1 or less than 1 (fig. 7).

Technic A modification described by Kraus¹² was used.

The disturbance of the cholesterol-cholesterol ester ratio is more pronounced the greater the degree of liver damage.

3 The Albumin/Globulin Ratio—Physiology This is described under cephalin-cholesterol flocculation tests in the section discussing which procedures differentiate between medical and surgical jaundice.

The degree of reversal of the albumin/globulin ratio depends on the degree of liver damage but to a certain

Fig. 7—Schematic drawing showing the relation between free and esterified cholesterol in normal persons and patients with liver disease.

extent on the development of ascites as well. Nevertheless, the albumin/globulin ratio and the absolute height of the albumin fraction is an especially valuable guide in the follow-up study in cases of cirrhosis.

4 Cephalin-Cholesterol Flocculation Test—The density of the flocculation varies directly with the degree of liver damage.

5 Takata-Ara Test—Physiology This is described in the section discussing which procedures differentiate between medical and surgical jaundice.

Technic The method of Jezler¹³ was used.

In chronic liver disease the variations in the number of test tubes showing precipitation is in direct proportion to the degree of liver damage.

WHAT INDICATES THE PROGNOSIS IN ACUTE HEPATITIS?

During the course of an acute hepatitis or the course of a superimposed hepatitis in cirrhosis sometimes a sudden turn for the worse due to breakdown of the liver may appear. The alarm symptoms of an imminent liver necrosis are similar to those of an approaching

secondary hepatitis in an obstructive jaundice. On the other hand, recovery may be ensuing while the jaundice is still unchanged. Here liver function tests chiefly indicate the dawn of recovery.

Signs of Alarm (Liver Failure)—1 Rise of the icteric index

2 Millon's test becomes positive

3 Drop in prothrombin level, only partly relieved by administration of vitamin K

4 Drop in the cholesterol esters

5 Rise of the nonprotein nitrogen

Signs of Recovery—1 Rise of the urinary urobilinogen in the face of a decrease in the bilirubinuria

2 Rise of the cholesterol esters

3 Increased diuresis

Physiology—During acute hepatitis the water avidity of the tissues is increased, producing a latent edema. In recovery this stored fluid is excreted. If the daily urinary output is charted, a sudden rise of the diuresis points to improvement.

4 Graham-Cole test becomes negative

Physiology—Tetraiodophenolphthalein is excreted into the bile in a concentration which does not give a shadow on roentgen examination of the patient. After concentration of the bile in the gallbladder the tetraiodophenolphthalein becomes sufficiently concentrated to produce a shadow on the roentgenogram. This shadow is not visible (positive Graham-Cole test) if (1) a damaged liver does not excrete the dye and the kidney excretes it, (2) in obstruction of the biliary passages, (3) in the presence of damage of the mucosa of the gallbladder which interferes with concentration of the bile and (4) if a gallbladder reflex emptying occurs before the roentgenogram is taken.

Generally in jaundice the Graham-Cole test will be positive whether the jaundice is due to hepatitis or to obstruction. In beginning recovery from hepatitis, however, the Graham-Cole test may become negative while some jaundice is still present.

LIVER FUNCTION CHANGES OF DIAGNOSTIC SIGNIFICANCE IN NONJAUNDICED PATIENTS

In the absence of jaundice, slight changes in the liver function from the normal may be significant. In the nonjaundiced patients the more sensitive liver function tests are indicated. There are many conditions in which liver function tests may be of diagnostic or therapeutic help in the absence of jaundice. The four most common situations in which these tests are useful are here discussed.

A. Early Cirrhosis—In a patient with a questionable early cirrhosis the demonstration of slight liver impairment will support the diagnosis.

The following findings are significant:

1 Increased icteric index

2 Increased urobilinogen in the urine

3 Bromsulphalein retention

Physiology—Bromsulphalein is normally excreted by the liver through the bile. In disturbances of biliary excretion, the blood level after the injection of a test dose remains high. This test is of no use in the presence of jaundice, since both hepatitis and obstruction interfere with the excretion of the dye.

Technic—Two mg. of bromsulphalein in a 5 per cent solution per kilogram of body weight is injected intravenously and the amount of dye retained is determined by comparing an alkalized serum sample (blood drawn from the other arm thirty minutes later) to

standards under the colorimeter. A retention of dye in more than traces is a sign of impaired biliary excretion and of liver damage in the absence of jaundice. The colorimetric readings permit a quantitative estimation.

4 Low albumin fraction and reversed albumin/globulin ratio

5 Positive Takata-Ara test

6 Dense flocculation of the cephalin-cholesterol emulsion

7 Low cholesterol esters

B. Chronic Gallbladder Disease—In some cases of chronic gallbladder disease without manifestation of jaundice, slight liver damage may be present, as demonstrated by the following tests:

1 Increased icteric index

2 Bromsulphalein retention

3 Dense flocculation of the cephalin-cholesterol mixture

4 Decreased hippuric acid excretion

C. In Controlling the Therapy with Hepatotoxic Drugs—Following the treatment with certain drugs (arsenicals, cinchophen, sulfonamide compounds and bismuth among others) hepatic jaundice may occur. This calls for immediate cessation of the therapy. With some of the drugs, however, especially the arsenicals, continuation of the therapy is sometimes desirable after the jaundice has subsided. Before such therapy is resumed liver function tests should be done to exclude persisting liver damage. In the presence of the latter, the therapy cannot be resumed. The status of liver function should also be determined whenever possible before treatment is started with a drug which may cause liver damage.

The following findings indicate impairment of liver function:

1 Increased urobilinogen in the urine

2 Bromsulphalein retention

3 Increased icteric index

4 Decreased hippuric acid excretion

5 Dense flocculation of a cephalin-cholesterol emulsion

D. Hyperthyroidism—In hyperthyroidism impairment of liver function may parallel the degree of thyrotoxicosis. Some¹⁴ feel that the impairment of liver function may serve as an indication of the disease equal to or even more reliable than determination of the basal metabolic rate.

The following tests seem to be useful in evaluating the presence and degree of liver damage:

1 Galactose tolerance test

In hyperthyroidism there is probably, in addition to liver damage, a faster intestinal absorption of galactose, which may raise the urinary excretion.

2 Hippuric acid excretion test

3 Bromsulphalein test

4 Cephalin flocculation test

In other more rare cases in which liver function tests are indicated in the absence of jaundice, the tests discussed will usually also be of aid.

SUMMARY

Liver function tests according to their usefulness in given situations are indicated in various clinical conditions.

¹⁴ Boyce, F. T. Factors in Mortality of Thyroid Disease in an endemic Area, Analysis of 817 Consecutive Surgical Cases and 103 Consecutive Surgical and Nonsurgical Deaths with Note on Value of Quantitative Test of Liver Function in Estimation of Hepatic Damage. *South. Surgeon* 9: 96-113 (Feb.) 1940.

In the differential diagnosis between surgical and medical jaundice, less sensitive liver function tests are required. In cases of prolonged jaundice the differential diagnosis may be impossible with any type of liver function test owing to the secondary hepatitis in obstructive jaundice. In the presence of jaundice the correct diagnosis can be made in the majority of cases by a good history, careful physical examination and simple qualitative urinary tests.

EMBOLIC ARTERIAL OCCLUSION OF LOWER EXTREMITIES

WITH REPORT OF FOUR SUCCESSFUL
EMBOLECTOMIES AND A REVIEW
OF THE LITERATURE

CAPTAIN ALBERT LESSER

MEDICAL CORPS ARMY OF THE UNITED STATES

The early recognition and operative treatment of embolic arterial occlusion of the extremities is still relatively infrequent. With the exception of the work reported by Swedish authors surgical interest and treatment in this condition has been comparatively scant until very recently. It is significant that Deitch¹ reports only 10 successful embolectomies in Great Britain up to 1936. I therefore believe that my recent experiences with 4 successful embolectomies warrants a report of these cases and a review of the subject of arterial embolism of the extremities.

ETIOLOGY

The most frequent cause of arterial embolus in the systemic circulation is a mural thrombus in the left auricle or left ventricle of the heart—in the left auricle as a result of rheumatic heart disease with mitral stenosis or degenerative heart disease with auricular fibrillation and in the left ventricle as a result of cardiac infarction from coronary occlusion. Other possible causes are the so-called paradoxical emboli arising from the peripheral veins or the right auricle and passing through a patent foramen ovale to the left side of the heart, also thrombi arising from the pulmonary veins or from the walls of proximal arteries or aneurysm. These embolic masses may be well organized hard or even arteriosclerotic plaques; this type usually lodges and remains in one piece. On the other hand the embolus may be soft and friable breaking off into many pieces after the original impact with the vessel wall. Emboli usually lodge at the site of bifurcation of major peripheral arteries blocking both branches. Key, in an analysis of 382 cases finds the bifurcation of the common femoral artery the most frequent site of embolic obstruction accounting for 55 per cent of all cases. The 4 cases to be here described occurred in the region of the common femoral or external iliac arteries.

The sequence of conditions occurring immediately following the impact of an embolus on a vessel wall presents an interesting corollary to the symptomatology, prognosis and treatment. A comparison of the embolus with the lumen of the vessel in which it lodges suggests that in many cases the immediate occlusion is due to the intense spasm of the vessel and the regional arterial tree affected. In about two hours, however, there is beginning formation of the distal secondary propagation thrombus. The distal secondary thrombus formation becomes so extensive after nine or ten hours and occludes so many collateral vessel orifices as to prevent return of circulation to an extremity even after operative removal of the embolus. This phenomenon emphasizes the rationale of combating vasospasm by the various measures to be discussed under therapy.

SYMPTOMATOLOGY AND DIAGNOSIS

The symptoms of sudden arterial occlusion are extremely variable and multiple. Severe pain is not always characteristic and the tendency to look for pain as the chief manifestation of embolism is probably responsible for the frequent failures to recognize the condition early. When pain does occur it is probably related to the intense arterial spasm of the distal vessel and collaterals initiated by the sudden impact of the embolus on the vessel wall. Thomas Lewis² believes that pain is due to ischemia of the muscles of the extremity involved and is therefore more significant in persons who have recently been active. In bedridden inactive patients muscle ischemia is not a pertinent factor and numbness and paralysis are more significant symptoms. Pain and tenderness along the course of the embolus and distal propagation clot are only late results. Pain itself may be present anywhere in the limb distal to the site of occlusion. Thus pain in the back would suggest occlusion at the bifurcation of the aorta. The variability of the pain factor is particularly attested in the cases reported in this paper since all the patients were partially or completely confined to bed for treatment of heart lesions at the time when the acute embolic accident occurred.

Other characteristic findings are absence of the peripheral pulses, a waxy whiteness or blotchy cyanosis of the skin, palpable coldness of the limb, impaired sensation, diminished reflexes and variable degrees of motor paralysis of the limb. A rather striking feature which was observed in my cases was a progressive diminution in the force and amplitude of the femoral pulse in embolism of the common femoral artery, as the hours elapsed a secondary thrombosis completed the extent of the mechanical occlusion of the vessel until the femoral pulse was gradually completely obliterated. De Takats⁴ points out that arterial embolism may have premonitory symptoms. A slight degree of numbness, tingling or coldness of the limb may appear days or weeks before the sudden complete vascular occlusion. These symptoms he believes to be due to the release of minute fragments from the central clot that is about to break loose.

Arterial thrombosis may be a complicating factor either as the original causative agent or as the agent

provoking recurrence of the occlusion after embolectomy has been performed. Arterial thrombosis usually originates on a background of peripheral arteriosclerosis and myocardial disease. There is frequently a previous history of intermittent claudication, coldness and discoloration of the extremities. Injury to the vessel intima as a result of arteriosclerosis and slowing of the circulation from myocardial disease with insufficiency are the important inciting factors in arterial thrombosis. The relationship of this condition to anticoagulant therapy will be discussed later in the paper.

Localization of the site of embolic occlusion does not usually present any great difficulty. The best clinical guide to the site of occlusion is the first bifurcation of the main arteries above the upper limit of physical findings (i. e., numbness, coldness, discoloration and the like). Thus, for example, in the lower extremity if the upper limit of physical findings is at the knee joint, the probable site of occlusion is the bifurcation of the common femoral artery. The explanation for the difference between the anatomic site of the occlusion and the level of physical findings is that the collateral circulation is usually well able to supply nutrient blood for a considerable distance beyond the site of occlusion, until, that is, occlusion of the collaterals also occurs as a late thrombotic process. Visualization of the site of block by means of arteriography has also been utilized but is frequently not practicable and usually not necessary.

TREATMENT

The prime requisite to proper therapy in acute arterial embolism of the extremities is a constant awareness of the possibility of such an accident by those treating patients with heart disease, thereby enabling prompt, early recognition of the condition. Every hour lost before treatment is instituted threatens not only the life of the limb but the life of the patient as well. The immediate measures to be taken in every early case are threefold: (1) relief of arterial spasm, (2) slowing of the blood clotting time to minimize intravascular thrombosis and (3) prompt operative embolectomy if a trial of conservative medical therapy has not restored the circulation.

Relief of arterial spasm can be effected by two measures: (1) the use of papaverine hydrochloride intravenously and (2) interruption of the sympathetic pathways by paravertebral block. The intense arterial spasm is believed to be responsible for the resulting pain and for the closure of collateral vessel openings distal to this site of occlusion. It is best combated by intravenous papaverine hydrochloride, in $\frac{1}{2}$ to 1 grain (0.03 to 0.06 gm.) doses, to be repeated at intervals of one hour. In a small percentage of cases papaverine has undoubtedly caused a sufficient release of spasm to permit the passage of the embolus beyond a major arterial bifurcation, permitting restoration of circulation by this conservative measure. However, McKee and Allen⁵ believe that if there is not a prompt restoration of circulation after the first or second intravenous dose of papaverine hydrochloride, further conservative therapy is useless and immediate operative embolectomy should be performed. My associates and I have continued the administration of papaverine hydrochloride postoperatively to control pain and combat any vascu-

lar spasm resulting from operative trauma. Graham⁶ advises the use of papaverine hydrochloride and other nonoperative measures, such as passive vascular exercise, only for cases seen too late for operative embolectomy. Griffiths⁷ reports poor results with papaverine hydrochloride and conservative measures such as paxan therapy, stating that such procedures merely caused prolonged delay and prevent early operative intervention. Denk,⁸ on the other hand, is confident that he has obtained satisfactory results in a fair number of cases by the intensive use of papaverine hydrochloride alone.

Linton⁹ states that the early use of paravertebral block to interrupt sympathetic pathways and counteract arterial spasm is useful in preventing blockage of collaterals and in controlling pain. Roome¹⁰ also reports the use of lumbar sympathetic block for the relief of pain and spasm following acute arterial occlusion but states that in his experience it has had no effect on the subsequent development of gangrene if embolectomy is not performed. Leriche¹¹ advises arteriectomy, that is, actual excision of the portion of the artery containing the clot, under the following conditions: (1) if operation is performed more than twenty-four hours after embolic occlusion, (2) if the endothelium under the embolus appears severely damaged and (3) if gangrene threatens despite embolectomy. He believes that this procedure abolishes reflex spasm above and below the site of obstruction.

It is our belief that conservative measures may be tried for four to six hours after occurrence of the embolic occlusion, and if after this time such measures have not caused prompt restoration of circulation immediate operative embolectomy should be performed. Or if six to ten hours have already elapsed since the onset of the occlusion, operative embolectomy should be performed without further delay.

TECHNIC OF OPERATION

The site of the operative approach is anesthetized with local infiltration of procaine hydrochloride. In all 4 cases here reported operation was performed at the site of the common femoral artery, a vertical incision extending from Poupart's ligament along the course of the artery a distance of about 4 inches. The femoral artery is gently mobilized, after the femoral sheath has been incised, and a complete cuff of adventitia removed from the wall of the artery with the aid of saline infiltration between adventitia and muscularis. Two bulldog clamps (or rubber shod Allis clamps) are placed proximal and distal to the embolic occlusion for control of arterial hemorrhage. With the clamps in place (under the specific control of an assistant), an incision is made axially through the vessel wall distal to the embolus. The organized embolic mass is identified and dislodged. The dislodged embolus is gently attempted by catheter suction or an

intra-arterial scoop The proximal bulldog or rubber shod Allis clamp is then opened *in situ* by the assistant and the intra-arterial blood pressure will usually force the embolic mass out through the arterial incision. If the embolus has been driven out in one piece, there will immediately follow a forcetful stream of blood under full arterial pressure and the assistant is instructed to close the proximal clamp. If such a forcetful arterial gush does not result the artery must be carefully investigated further proximally to dislodge one or more additional embolic masses higher up, possibly in the region of the external iliac. Such intra-arterial probing must be done extremely gently with as little trauma to the intima as possible. When a forcetful arterial flow has been obtained, the proximal clamp is replaced and the distal clamp is opened. If no blood flow results from the distal vessel, it is probably occluded by a propagation thrombus, which must be carefully dislodged by catheter suction or careful, gentle intra-arterial manipulation. The degree of organization, its extent and adherence to the vessel intima will depend on the length of time elapsed between the onset of the occlusion and the operation. In 1 of our cases the distal propagation thrombus removed in one piece measured 14 inches. When full arterial flow has been reestablished from both proximal and distal openings of the artery closure of the axial incision in the artery is performed by a careful continuous eversion suture of fine black silk affecting approximation of the intima in eversion. Whenever necessary several interrupted sutures are taken to control bleeding from the incision in the artery when the clamps are removed. As soon as closure of the arterial wall is completed, a full arterial pulsation can be seen transmitted down along the distal vessel and in some cases there is immediate restoration of warmth, color and peripheral pulsation in the lower limb.

The basis for the use of heparin in thrombosis and embolism has been thoroughly established by Murray¹² and Best in intensive studies. We have essentially followed their technique of administration as follows. The heparin solution is added to an intravenous saline drip. Usually 1,000 units of heparin, i. e., 10 mg. is added to each hundred cubic centimeters of saline solution. The saline and heparin mixture is allowed to run into the vein at such a rate that the clotting time of the patient's blood is maintained at about fifteen minutes, i. e., two or three times the normal value. The rate at which the solution runs in is usually about 25 drops a minute but may vary from case to case. The clotting time may be determined by one of the simple methods such as the breaking off of bits of a capillary tube filled with blood obtained by superficial capillary bleeding. In cases in which there is associated heart failure when administration of large amounts of intravenous fluids was contraindicated McClure and Lam have used the injection of undiluted heparin, repeated every three hours, with satisfactory maintenance of the clotting time at about fifteen minutes, that is using about 100 mg. every three hours. By the continuous intravenous drip method, about 20 to 25 mg. an hour is sufficient to maintain the clotting time at the desired level. We have used the intermittent administration of undiluted heparin as required by the cardiac status of the patient

with satisfactory results. The need for an antiheparin is rather unimportant since the clotting time returns to normal within one hour after its administration has been stopped. We have made it a practice to begin the administration of heparin as soon as the diagnosis of an embolic arterial occlusion is made, and it is continued whenever feasible for ten days, by which time it is felt that adequate reestablishment of circulation has taken place. The preoperative administration of heparin makes for rather a bloody field at the operative site but has in no way interfered with hemostasis or healing of the operative wound.

All instruments and suture materials are kept immersed in sterile liquid petrolatum and the operative field is kept constantly flushed with a warm 2 per cent solution of sodium citrate. Very fine black silk on an atraumatic eye needle is used for arterial suturing and hemostasis. When the operative procedure is completed the limb is carefully wrapped in thick cotton batting reinforced with flannel bandage from the toes to the groin. Postoperatively, general body warmth is maintained and heparin and papaverine hydrochloride administration are continued for five to ten days, depending on the rapidity with which a satisfactory clinical result is obtained.

PROGNOSIS

Most authors are in agreement that a living limb one month after embolectomy may be considered a successful result. Key,¹³ in a study of a series of 382 cases in Sweden, states that prognosis depends on the following factors: 1 The mortality rate of limb and patient rises rapidly after six hours following the occurrence of the acute embolic occlusion. 2 The poor general condition of patients subject to embolic occlusions militates against successful results. 3 Previous arteriosclerosis and rough handling of the vessel involved during operation predisposes to postoperative thrombosis involving collateral vessels as well as the main vessel.

Of this series of 382 cases Key reports that in 22 per cent the operation was successful, in 18 per cent subsequent amputation was required and in 60 per cent the patient died in the hospital within one month after the operation. Of sixty-six embolectomies performed on the iliac vessels, only ten were successful.

Griffiths states that the numerous failures after embolectomy are due to prolonged delay, late recognition of the condition and time consuming attempts at conservative therapy after operative treatment has been instituted. Danzis, in a review of case reports from the literature, found that there were 60 per cent successful results among those patients operated on within the first four hours and only 18 per cent successful results among those operated on after twelve hours. Of those patients not receiving embolectomy 13 per cent had amputations and 87 per cent were dead within two weeks after the acute embolic occlusion. The latest operation with a successful result was that of Holst in which a femoral embolectomy was done twenty-seven hours after occlusion.

Graham offers the following as the causes of failure of restoration of circulation to the limb after embolectomy: (a) recurrent embolic accidents, (b) preexisting organic disease of the peripheral arteries and (c) reformation of the thrombus on the damaged intima.

Lund,¹³ in another review of a large group of cases in Sweden, states that the patients who did not have in embolectomy nearly all died within a short period of time whether they had gangrene and amputation or not. Of those patients successfully operated on, 25 per cent were dead in one year, 50 per cent in three years, 60 per cent in five years and 85 per cent in ten years.

REPORT OF CASES

CASE 1—H. B., a white man aged 49, admitted to the medical service of the Metropolitan Hospital on April 22, 1941, complained chiefly of difficulty in breathing and swelling of the scrotum and ankles of one year's duration, which had become progressively worse. He had previously been hospitalized elsewhere for the same complaints. Significant physical findings at the time of admission were auricular fibrillation, systolic murmur at the cardiac apex, a blood pressure of 130/80 moist rales at both lung bases, liver enlarged 5 cm. and tender to palpation, questionable presence of ascitic fluid and 1 plus edema of the ankle. An electrocardiogram indicated auricular fibrillation, severe myocardial damage suggestive coronary artery disease, possibly rheumatic. Therapy consisted of mercurpall, digitalis theophylline with ethylenchamine, clinical improvement was good until May 15, when the patient experienced a sudden severe pain in the left foot with a feeling of coldness and numbness in the left leg and thigh. Examination about one hour after the onset revealed cyanosis, coldness and

Specimens removed at operation in case 3. Above, multiple, hard organized, embolic masses removed through opening in common femoral artery; below, single distal tail-like propagation thrombus 14 inches in length removed retrograde through opening in common femoral artery.

diminished sensation of the left leg up to the knee. All peripheral pulses were absent with the exception of the femoral, which was poorly palpable. Oscillometric readings were completely absent below the groin. Operation was performed four and one-half hours after the embolic accident, through a longitudinal incision in the upper part of the left thigh under local anesthesia. The common femoral artery was exposed and incised longitudinally. An embolic mass about $\frac{1}{2}$ inch in diameter was removed without resulting bleeding; a probe was inserted proximally toward the external iliac, with gradual loosening of an additional embolic mass, which was forced out of the incision in the femoral artery with a terrific gush of bleeding; this mass was about 2 inches in length, hard and well organized. Suction applied to a soft rubber catheter in the distal femoral artery removed a soft tail-like thrombus about 6 inches long. Closure of the artery and wound was performed, heparin therapy was carried out as described. Normal warmth, sensation and circulation were restored to the left leg about the fifth day after operation.

On May 27, twelve days after the embolic accident to the left leg, the patient began to complain of increasing numbness, coldness and paralysis in the right leg. These symptoms were of about eleven hours' duration before the patient thought them important enough to report to the intern. Examination revealed a mottled discoloration, coldness and diminished sensation up to about the knee. All pulses except the femoral were absent, and oscillometric readings were absent below the midthigh. Operation was performed about twelve hours after onset of symptoms, with removal from the common femoral artery of an embolic mass 1 inch in length, there was an immediate gush of blood

proximally, and on removal of an 8 inch long distal propagation thrombus there was brisk bleeding from the distal femoral artery. The usual closure and postoperative therapy were carried out and satisfactory restoration of circulation to the limb was evident on the second day after operation. Of some interest are the tissue examination reports of the specimens removed at operation; the mass obtained at the first operation showed the usual firmly organized thrombus, whereas the embolus removed at the second operation revealed a decided purulent involvement of the organized clot. The patient was discharged from the hospital and has been under treatment in the cardiac outpatient department. Examination of the extremities about one year after the second embolectomy revealed both limbs to be warm and of normal sensation, with moderate edema about the ankles; the patient has had no complaints referable to the extremities.

CASE 2—M. H., a Negro aged 26, admitted to the surgical service of the Metropolitan Hospital on April 25, 1941, complained chiefly of progressively increasing pain in the right upper quadrant of the abdomen of five days' duration. There had been no nausea or vomiting until the day of admission, when the patient vomited three times with definite aggravation of the pain in the right upper quadrant. There was no other significant past history. Physical findings at the time of admission were as follows: temperature 99.4 F, pulse rate 100 and respiratory rate 28. The abdomen was moderately distended and tympanic, with exquisite tenderness, muscle resistance and hyperesthesia in the right upper quadrant. There was a sinus tachycardia with reduplication of the second sound, the blood pressure was 142/100, the white blood cell count 14,600 with polymorphonuclear leukocytes 88 per cent, urinalysis was negative except for a faint trace of albumin. The admission diagnosis was acute cholecystitis. The patient was treated expectantly for three days, and with no evidence of clinical improvement and a rising white blood count cell laparotomy was performed. The gallbladder and ducts were entirely normal, and no other intra-abdominal disorder was found except slight enlargement and hyperemia of the liver. Postoperatively the patient continued to have a spiking temperature with persistent tachycardia and increasing dyspnea, on repeated occasions he had episodes of severe pain in the left lower quadrant, the right lower quadrant and the left kidney region. An electrocardiogram showed auricular changes and myocardial damage. Blood cultures were repeatedly negative and urines showed granular casts. The Wassermann reaction was reported 3 plus. On May 29 (approximately one month after the onset of illness) the patient complained of coldness and loss of feeling and power in the right lower extremity. Examination revealed all pulses absent below the femoral artery, coldness, impaired sensation and absence of oscillometric readings below the right groin. A diagnosis was made of embolic occlusion of the right common femoral artery and operation was performed fourteen hours after the first onset of leg symptoms. An embolic mass about $\frac{3}{4}$ inch in diameter was removed from the common femoral artery and a long tail-like thrombus 8 inches in length was removed from the distal femoral artery with full restoration of femoral bleeding. The usual operative and postoperative technique was followed. On the third day after operation the right lower extremity was warm and had regained normal sensation, the peripheral pulses were still not obtainable. The medical condition persisted unchanged and medical consultation was of the opinion that the entire clinical picture could be explained on the basis of an active myocarditis with mural thrombi and repeated visceral and peripheral embolic episodes.

CASE 3—F. K., a white woman aged 64, admitted to the Flower and Fifth Avenue Hospitals on Sept. 29, 1941, had been under treatment for the past year for auricular fibrillation with mild cardiac decompensation. During the previous three weeks she had complained of precordial pain, palpitation and dyspnea. About twelve hours prior to admission the patient complained of severe pain in the calf of the right leg followed by a sensation of weakness and numbness in the leg. She massaged the leg and applied a hot water bottle to the calf region before calling her family physician, who made a diagnosis of embolic occlusion. Repeated intravenous papaverine hydrochloride was unsuccessful and operative intervention was advised. At the

¹³ Lund C. C. The Treatment of Embolism of the Greater Arteries. Ann. Surg. 106: 880-909 (Nov.) 1937.

time of admission to the hospital about twelve hours after the occurrence of the accident the right leg was cold and cyanotic with patches mottling up the knee, almost completely insensitive and showing evidence of a second degree burn of the calf region. Occlusive readings were not obtained below the groin. The heart was enlarged to the left and downward, with clinical evidence of auricular fibrillation, an enlarged tender liver and a moderate amount of pulmonary basal rales. The blood pressure was 128/80. Operation was performed about thirteen hours after onset by the usual technique, it was noted on the operating table that the femoral pulse which had previously been palpable could no longer be obtained. When the common femoral artery was opened there was no bleeding. By combined careful probing and catheter suction several hard organized embolic masses were expelled from the opening in the femoral artery followed by a powerful gush of bleeding. There was no bleeding from the distal femoral artery. Catheter suction was applied and a single tail like propagation thrombus about 14 inches in length was removed, followed by free active bleeding from the distal femoral. Almost immediately after repair of the arterial wound the foot and leg were warm to palpation and peripheral pulses were felt. Postoperative convalescence was entirely normal except for separation of the burned skin from the calf and great toe. Excellent vascular granulations and filling in took place in a comparatively short time. At the last follow up examination nine months after operation the patient was up and about moderately active and under good cardiac regulation she had, however developed a progressive psychosis apparently on a cerebrovascular basis.

SUMMARY

1 A survey of the recent literature emphasizes that prompt operative intervention (within six to eight hours after acute embolic occlusion) offers a good prognosis for a live limb and a live patient.

2 Of those patients not receiving the benefit of embolectomy about 90 per cent die within two weeks, whether amputation is performed or not.

3 Patients under treatment for chronic cardiovascular disease should be constantly observed for the possibility of an acute embolic occlusion of the extremities.

4 Arterial embolectomy of the extremities is a simple safe operative procedure performed under local anesthesia, with no mortality rate per se.

5 The introduction of heparin therapy has remarkably facilitated the surgery of embolism and has minimized the danger of recurrent thrombosis.

6 The attempts at conservative treatment of acute embolic occlusion should not be prolonged beyond six hours after occurrence of the accident, if these measures are unsuccessful after a six hour trial immediate surgery should be performed.

7 Of the four successful embolectomies reported two were performed on 1 patient for two separate embolic accidents. The number of hours elapsed between the onset of embolic arterial occlusion and the time of operation were respectively four and one-half hours, twelve hours, fourteen hours and thirteen hours.

Intuition in Science—We often underrate the importance of intuition. In almost every scientific problem which I have succeeded in solving even those that have involved days or months of work the final solution has come to my mind in a traction of a second by a process which is not consciously one of reasoning. Such intuitive ideas are often wrong. The good must be weeded out from the bad—sometimes by common sense or judgment—at other times by reasoning—Langmuir. *Irving Science Common Sense and Decency* *Science* 97:1 (Jan 1) 1943.

USE OF PENICILLIN IN SULFONAMIDE RESISTANT GONORRHEAL INFECTIONS

WALLACE E. HERRELL, M.D.

EDWARD N. COOK, M.D.

AND

JUTHIE THOMPSON, Ph.D.

ROCHESTER, MINN.

The preparation of a highly concentrated and active form of penicillin was first reported by Chain, Florey and others¹ in 1940. In 1941 Abraham and others² reported more extensively on their investigative studies including the first clinical trials. They mentioned that the growth of six different strains of *Neisseria gonorrhoeae* was inhibited in dilutions in the order of 1:2,000,000. Another strain was inhibited only up to 1:32,000. These investigators, however, pointed out that the actual figures reported must be taken with reserve because the potency of the penicillin varied as the work progressed. At the end point was based on twenty-four hour readings the results may indeed vary considerably. Subsequent experience largely has confirmed this early work.³ Herein we report experimental and clinical results with *Neisseria gonorrhoeae*. While we have prepared small amounts of penicillin the material used in our studies was furnished for the most part through the courtesy of Abbott Laboratories Incorporated.

Because of the limited amounts of penicillin available it did not seem justifiable to use penicillin in gonorrheal infections which are fairly amenable to sulfonamide therapy. The need, however, is apparent for an effective therapeutic agent against infections due to this organism which are known to be resistant to sulfonamide preparations. We elected therefore to study the effect of penicillin experimentally against several strains of *Neisseria gonorrhoeae* isolated from patients in treatment of whom adequate sulfonamide therapy had failed.

EXPERIMENTAL DATA

In vitro tests to determine the bactericidal action of penicillin on *Neisseria gonorrhoeae* were done in the following manner on three strains of the organism. A laked blood base was used for the test because by previous experience it had been found the most satisfactory method for preserving the viability of *Neisseria gonorrhoeae*. It was made by adding to sterile distilled water an equal amount of sterile citrated blood. Two different lots of penicillin were used, the first of which contained 174 Oxford units per milligram and the second 230 Oxford units per milligram. A primary dilution of 1:500 was made of the first lot and a com-

parable dilution in terms of Oxford units was made of the second lot which was also considered to be 1:500 for the purpose of this experiment. These primary dilutions then were used to make the higher dilutions of penicillin in the laked blood base. Preliminary trials showed that dilutions of 1:100,000 and 1:200,000 were most suitable for the tests since the end point in the test could be reached before there was any great

+++ heavy growth, ++ moderate growth, + slight growth, 0, no growth

reduction of numbers of the bacteria in the control tubes. A heavy suspension of *Neisseria gonorrhoea* was made in 1 cc of the laked blood base by removing the growth from the surface of a chocolate blood agar plate which had been incubated from twenty-two to twenty-four hours. Enough of this heavy suspension was added to the dilutions of penicillin in laked blood and to the control tube of laked blood so that if a 3 mm loopful was streaked at once on a chocolate blood agar plate the resulting culture would show between 300 and 400 colonies. The tubes were placed in an incubator at 37 C and subcultures were made on chocolate blood agar at hourly intervals from the test dilutions and from the control tube.

The results obtained are shown in table 1. It was noted that there was a sharp drop in the number of viable organisms in contact with penicillin between the first and the second hour in strains 1 and 3 and between the second and the third hour in strain 2. Table 1 also shows that all the organisms in contact with the dilutions of penicillin were no longer viable after three or four hours while the control tubes still had large numbers of viable organisms. It was apparent that after four hours there was some reduction of the number of organisms in the control tubes, and for that reason it was thought best to use such dilutions of penicillin as would give an end point within that period.

CLINICAL TRIALS

Penicillin, in addition to being antibacterial for the organism, fortunately is excreted rather rapidly in the urine. The twenty-four hour urine of patients receiving the amounts of penicillin used will usually contain approximately 3 Oxford units of penicillin per cubic centimeter of urine. In other words, between a third and a half of the material is excreted through the urinary apparatus. This is, of course, highly desirable in the treatment of infections of the type being considered. The high degree of solubility of the material also permits it to reach the involved tissues readily. From these observations, therefore, it seemed entirely logical to expect satisfactory clinical results from the use of penicillin in the treatment of infections due to *Neisseria gonorrhoea*.

In view of the highly effective antibacterial activity of penicillin against these strains of *Neisseria gonorrhoea*, the 3 patients from whom they were isolated

were treated with the intravenous administration of penicillin according to the method recently described by one of us.⁴ For the treatment of these infections the largest amount of penicillin administered in twenty-four hours was 32,000 Oxford units. Half of the twenty-four hour dose was dissolved in 1 liter of isotonic solution of sodium chloride. If for any reason the administration of isotonic solution of sodium chloride is undesirable, penicillin may be administered in a 5 per cent solution of dextrose in triple distilled water without any loss of activity. Initially between 100 and 200 cc of the material is administered intravenously at a fairly rapid rate. Following this the rate of injection is regulated to between 30 and 40 drops per minute. The second liter containing penicillin may be attached to the continuous intravenous system eight to ten hours later. Repeated venipunctures may be avoided by allowing the solution of dextrose to drip in slowly during the interval in which penicillin is not being administered. A simple arm splint is applied to keep the arm in position. This is tolerated well by the patient and renders the continuous intravenous administration possible and not uncomfortable. When pyrogen free penicillin has been used, no toxic reactions have been observed. The solution containing penicillin is made up immediately before use. There is no evidence of loss of potency of the material which is kept in the closed system and is administered in the manner described. It should not be overlooked that administration of the solution of penicillin is continuous rather than intermittent.

A summary of the amounts of penicillin used, the number of days of administration and the results in the 3 cases herein reported is shown in table 2.⁵ The rather striking and early clinical improvement together with the complete lack of any toxic effect due to administration of penicillin was gratifying.

CASE 1—A white man aged 30 presented himself because of a urethral discharge which had persisted for thirty days. The urethritis had its onset six days after exposure. He was treated immediately with an adequate course of sulfathiazole but nothing more than temporary improvement was obtained. He received another course of sulfathiazole as an ambulatory patient without any apparent effect. He then was hospitalized for a third attempt at chemotherapy.

TABLE 2—Penicillin Therapy in Sulfonamide Resistant *Gonorrhea*

Case	Smear	Chocolate Blood Agar Culture	Penicillin		Days Treated	First Negative Culture Hrs	Result
			Total, M _g	Oxford Units			
1	Positive	Positive	340	68,000	2½	17	Cure
2	Positive	Positive	391	92,000	3½	48	Cure
3	Positive	Positive	442	104,000	3½	48	Cure

At the time of his admission a complete general examination gave negative results. There was a copious urethral discharge which on smear and culture showed the presence of *Neisseria gonorrhoea*. The genitalia were normal otherwise. The prostate was slightly enlarged and tender. The complete blood examination, including a flocculation test for syphilis, gave entirely normal results. The routine examination of urine revealed a slight amount of albumin, and the microscopic examination showed an occasional erythrocyte and pyuria, grade 4 on the basis of 1 to 4.

⁴ Herrell, W. E. Further Observations on the Clinical Use of Penicillin, Proc Staff Meet, Mayo Clin 18:6576 (March 10) 1943.
⁵ Since this paper was submitted for publication we have used penicillin in 2 additional cases of sulfonamide resistant gonorrhea. In 1 case, in which the infection had been present for four months, the cultures became negative forty-eight hours after the administration of penicillin was started. In the other case the infection had been present for eleven months and the first negative culture was obtained in twenty-one hours.

The patient was hospitalized and penicillin therapy was begun. Penicillin was administered by the intravenous drip method. The first liter contained 16,000 Oxford units and its administration was started at 5 p. m. on the day of his admission. Five hours after the treatment was begun the patient stated that the dysuria and urethral distress had subsided completely. By 10 a. m. the following day there was no urethral discharge, and no material could be obtained even after prostatic massage. In other words the patient was free from symptoms within seventeen hours after the institution of penicillin therapy. Prostatic secretion and first urine cultures taken seventeen hours after the institution of treatment did not reveal any *Neisseria gonorrhoeae*. Another attempt at culture was made twenty-four hours later but the results were completely negative. Forty hours after the institution of treatment routine urinalysis did not reveal any albumin, and the microscopic examination revealed no erythrocytes and only an occasional pus cell.

During the first twenty-four hours the patient received 2 liters of the penicillin preparation, which represented a total of 32,000 Oxford units, or 160 mg. For the second twenty-four hours he received 2 liters of the penicillin preparation, each containing 12,000 Oxford units or a total of 24,000 units for the second twenty-four hours. He received 1 more liter of penicillin after this which contained 12,000 Oxford units and because of the complete absence of any clinical findings treatment was discontinued and he was dismissed. Ten days later the patient returned for examination. He had been completely well and cultures taken after he had imbibed alcohol rather heavily and following coitus were entirely negative. The patient has remained entirely free from symptoms.

CASE 2—A white man aged 29 had been ill for five weeks. He had had a persistent purulent urethral discharge due to a gonorrheal infection contracted following exposure shortly before his illness. He had received sulfathiazole, sulfanilamide and finally sulfadiazine in amounts which would be considered quite adequate. Six days before admission there had developed acute urinary retention which required catheterization for relief. At that time purulent urine was obtained. Severe bilateral pain in the lower part of the abdomen had developed with some extension into both flanks. The patient suffered a great deal of pain during the act of urination and there were extreme frequency and urgency. His temperature ranged between 99 and 101 F. The prostate was enlarged, grade 4. It was extremely tender and the possibility of a prostatic abscess was considered. Examination of the abdomen revealed extreme tenderness and muscular spasm in both lower quadrants. There was also some tenderness in both lumbar areas. The temperature on admission was 101 F. The remainder of the physical examination gave negative results.

The routine urinalysis did not reveal any albumin or sugar. Microscopic examination revealed occasional erythrocytes and pyuria grade 2 with 50 cells per field. The concentration of hemoglobin and the erythrocyte count were normal. However, the leukocyte count was 14,600 per cubic millimeter of blood and the sedimentation rate was 94 mm per hour. Cultures of the prostatic secretion and first urine revealed many gonorrheal organisms present.
